INDEX TO VOLUME I FOR 1926.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma, Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Light, Roentgen, Radium, X Rays; Status Lymphaticus and Thymus; Eye, Ophthalmia, and Vision; Bicycle and Cycle; Motor and Automobile; Association, Institution, and Society, etc. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Correspondence," "Leading Articles," "The Week," "Reviews," etc. Original Articles are indicated by the letter (O).

A.

Abdomen, the acute, in childhood (Gertrude Herzfeld), 618

Abdominal disease, review of books on, 532

Abdominal disorders in childhood (F. J. Poynton), 529

Abdominal fibroma (Louis Cassidy), 946

Abdominal operations, appendicostomy for the relief of thirst and inanition after (H. de Lisle Crawford), 236 (O)

Abdominal operations, review of books on, 702

Abdominal torsion of omentum. *See* Omentum

ABEL, H. M.: Life assurance medicine, 99

ABEL, J. J.: Crystalline insulin, 666

ABENICROMBIE, G. F.: X-ray diagnosis of triplet pregnancies, 376

Aberdeen. *See* Scotland

arthritis, 867

Abrams' boxes for hire, 207

Académie de Médecine: Sea-sickness and sea voyages, 216—Buisson prize awarded, 309—Prince Albert of Monaco prize awarded, 461—Army Medical Service in France, 586—Foreigners in Paris hospitals, 631

ACADEMY, ROYAL, OF MEDICINE IN IRELAND: Danger of small-pox, 300

Section of Anatomy and Physiology.—Hypoplasia, 289—The relation of the blood flow through the kidney to urine excretion, 1037

Section of Medicine.—Sarcoma of the spinal cord, 531—Lymphosarcoma of the lung, 531—Malarial treatment of general paralysis, 865—Scleroderma, 867—Clinical cases, 867—Tubercle of the skin simulating leprosy, 867—Alkaptonuria, 867—Syphilitic disease of bone simulating rheumatoid arthritis, 867—Electrocardiogram of a case of paroxysmal tachycardia, 867—Electrocardiogram of a left bundle branch block, 867—Radiotherapy in blood diseases, 993—Alkaptonuria, 993

Section of Obstetrics.—Sarcoma of the uterus, 378—Tuberculous salpingitis, 654—Pregnancy complicated by poly cystic disease of the kidneys, 945—Abdominal fibroma, 946—Carcinoma of the cervix following posterior division, 1034

Acute bacterial, bacteriology, surgery, 20—Foreign body in the brain, 195—Infantism due to polyposis of the colon, 196—Double vesiculotomy, 196—Carcinoma of the rectum, 426—X-ray treatment of exophthalmic goitre, 692—The rationale of radium treatment of middle-ear deafness, 1085

Accidental haemorrhage. *See* Haemorrhage

Accidents: Fatal, in coal and iron mines (parliamentary note), 407—Industrial (parliamentary note), 512—Industrial, statistical investigation of (E. M. Newbold), 713—Industrial, review of book on, 743—Railway, during the strike (parliamentary note), 838

Accommodation, the mechanism of (E. F. Fincham), 75

Accumulator, the tungstone, 949

Acetylsalicylic acid for relief of the lightning pains of tabes, 890

ACHARD, Charles, re-elected general secretary of the Académie de Médecine, 125—A condemnation of apéritifs, 157—*Cinq Leçons sur le Diabète*, rev., 430—*Clinique Médicale de l'Hôpital Beaujon*, rev., 580

ACOMB, L. Ernest (and T. I. CANDY): Full-time ovarian foetation, 320 (O)

Acriflavine injections for tuberculosis (G. H. Johnson), 567

Acro-cyanosis (W. Calwell), 218

Acromegaly, case of (Postor Coates), 285—(A. W. Hendry), 830

Acromio-clavicular joint, dislocation of (James Riddel), 697

Actinomycosis, abdominal (S. C. Shaw), 701

Actinomycosis of the appendix (C. F. J. Baron), 233

Actinomycosis successfully treated by iodine in milk (Hubert Chitty), 418 (O)—Correspondence on, 682

Actinotherapy and heliotherapy, 167

Acute abdomen. *See* Abdomen

ADAMS, James: *Asthma and its Radical Treatment*, rev., 947

ADAMS, J. G.: Lead in treatment of malignant disease, 569, 591—Return from America, 680

ADAMS, George Edward D'Arcy, obituary notice of, 725

ADAMS, Joseph: Hunterian Lecture on the surgery of the jejunum, 646 (O)

ADAMSON, R. O.: The medico-legal problem of insanity, 141

ADDISON, Thomas: Commemoration meeting, 1096

Addison's disease, the blood sugar in a case of (E. F. Chapman), 323

Adenofibroma of the ovary (Herbert Spencer), 992

Adenoma of kidney (R. V. Solly), 702

Adenoma malignum (Herbert Spencer), 574

Adenomyoma of recto-genital space and sarcoma of ovary, 145

Adeno-tonsillectomy, the technique of (James C. G. Macnab), 236 (O)

ADIE, W. J.: Obscure pyrexia in adults, 482

Adoption of Children Bill, 405, 512

ADRIAN, E. D.: The impulses produced by sensory nerve endings, 1000

Advertisements by post, 976

Aeronautics: early, medical men in (F. J. Forrester), 259—*See also* Aviation

A British Medical Association Lecture

ON

CANCER OF THE COLON.*

BY

CHARLES A. PANNETT, M.D., F.R.C.S.,

PROFESSOR OF SURGERY, UNIVERSITY OF LONDON; SURGEON TO
ST. MARY'S HOSPITAL.

THE colon is one of the sites where, when malignant disease develops, operative treatment can effect a great deal. It therefore has urgent claims to careful consideration.

In itself, cancer of the colon is only a relatively common condition. At St. Mary's Hospital, during 1924, no more than 12 cases were admitted to the practice of all the surgeons. The general practitioner can scarcely expect to see more than one case in two or three years. Considering such facts, it is amazing that he recognizes the disease as early as he does, for the diagnosis is by no means always easy. Vague symptoms may suggest, but the most modern investigations may be unable to prove, its presence. There is nothing for it but an exploratory operation—not to be advised lightly at the time of life when malignant disease prevails—or a waiting policy of careful observation. Decisive symptoms will eventually make their appearance, but by this time effective treatment may not be simple to carry out, and perhaps may be impossible.

Some Difficulties in Diagnosis.

I need not remind you that the scirrhus growth tends to encircle the bowel and call attention to its presence by attacks of obstruction. This is the commonest clinical picture. Yet it is not always easy to recognize.

A youngish woman had several attacks of abdominal pain lasting a few hours only, spread over eighteen months. She never called in her doctor until the subsidence of the attack, when a most careful examination failed to reveal any clinical objective sign. One day the pain persisted. Her doctor was able to feel a distended caecum. The diagnosis was made, but the growth of the ascending colon had spread beyond the bowel and was irremovable. It had, in fact, become adherent to the right kidney and perforated into the extraperitoneal tissues, where it had given rise to a small abscess.

Recurrent attacks of pain in the abdomen, accompanied by constipation, need careful investigation, especially if there has been a gradually increasing trouble with the bowels. These patients often come to us complaining of indigestion and pain after food. It is due to the peristalsis which is called forth by the entry of food into the stomach. They say that their appetite has failed. Sometimes there is a call to stool after each meal—a very suspicious occurrence. Aperients always give them excessive pain, and they notice very often that there is much rumbling from wind within the bowels. The examination of the abdomen between the attacks of pain may throw no light on the condition. During the attack careful palpation will reveal the characteristic elastic feel of a distended caecum, which will appreciably harden and relax under the hand. This is the only part of the large intestine which can ever be felt to contract. The caecum always bears the brunt of the pathological process when an obstruction is situated

in the large bowel, for reversed peristalsis seems to force the intestinal contents back against the ileo-caecal valve. The caecum distends more than any other part; it is the usual part to rupture in a neglected case and the first to necrose from bacterial infection.

In about 40 per cent. of cases a tumour is felt. This tumour is not always the growth itself, which is of quite small bulk, but a mass of faeces impacted above the constricted area. Such tumours disappear after the bowel has been emptied with an enema. The disappearance of a lump in this way does not remove the suspicion of a new growth being present. Further observation and examination are required before a diagnosis of simple faecal impaction can be confidently made. The commonest site for carcinoma to grow is somewhere in the sigmoid loop, and the normal situation of this part of the bowel is in the pelvis. By rectal examination the finger can not infrequently detect through the thin rectal wall a growth of the sigmoid colon. This examination should never be omitted, for by it not only is a growth in the rectum excluded, but a growth which is sometimes hidden to x-ray examination is definitely revealed. The following two cases are interesting as showing how difficult diagnosis may be.

CASE I.

B. C., a girl aged 23 years only, suffered from a number of attacks of abdominal pain spread over eighteen months. They were of short duration, and only once was she laid up. The pain came on after food. She suffered from nausea and lost her appetite. In the worst attack she vomited, and the pain was referred to the epigastrium and the right iliac fossa. Her bowels were regular all through. Her doctor in this attack found tenderness in the right iliac fossa. Appendicitis was diagnosed, and a month later she came into hospital. There were no physical signs at this time, and, because of this and the fact that she had complained of cramps of the right leg, cystoscopy, pyelography, and renal x-ray examinations were performed. No indication of renal disease being discovered, appendicectomy was performed. Externally the caecum and appendix looked normal, but on cutting open the latter its mucosa was obviously inflamed. She went home, and a month later had an attack of acute obstruction. She was operated upon and a ring carcinoma of the transverse colon was found. I am glad to say I was able to resect this and reconstitute the alimentary canal. It is interesting to note how the pain was referred to the distended caecum, which was tender, so that appendicitis was simulated, and the colitis, always present above a growth, had extended to the mucosa of the appendix, so misleading me even after it was removed. The condition, too, occurred at an exceptionally early age.

CASE II.

H. W., a woman aged 30, about to be married, had an acute attack of pain in the left hypochondrium accompanied by vomiting, and was admitted to hospital with a temperature of 101° and a pulse of 118. She was rigid and tender over the affected area, and also in the renal angle behind. No lump could be felt. She had had a very minor attack of similar nature two months before. She said she had always been constipated. A perinephric infection was suspected, but the leucocyte count was only 11,600; cystoscopy showed no abnormality, nor did examination of the urine. The attack gradually subsided, and then a barium enema revealed an obstruction just beyond the splenic flexure. This proved to be a carcinoma, which was excised and the bowel continuity restored.

This case illustrates another clinical point—namely, the liability to local infective attacks. The surface of the growth is ulcerated and gives access to organisms which, penetrating the wall of the bowel, set up a local inflammatory process. The general condition of a patient with a stenosing scirrhus growth is often strikingly good. The condition remains latent until mechanical obstruction

* Delivered before the Isle of Thanet Division of the British Medical Association on October 11th, 1925.

causes abdominal symptoms to arise. In excluding cancer of the bowel no reliance at all can be placed upon a healthy aspect, a clear complexion, youth, or an absence of wasting.

But there is another type of growth—the fungating variety, which projects as a cauliflower growth into the lumen of the bowel, but shows little tendency to encircle it and sometimes none to obstruct it. These tumours always ulcerate, and the infection which takes place plays the most important part in the production of symptoms. There is no constipation, but nearly always diarrhoea. The general symptoms are pronounced. There is the wasting and cachectic appearance of toxic absorption and an irregular temperature. Such growths are quite likely to be diagnosed as a simple colitis.

CASE III.

C. M., a country denizen aged 60, suffered for two and a half years before admission to hospital. He complained of pain under the left costal margin, aggravated by food, vomited occasionally, and for the last eight months had had an irregular temperature. In the left hypochondrium was felt a tumour. The abdomen was not at all distended. The caecum could not be felt. An irremovable malignant growth was found at the hepatic flexure. An anastomosis was made between the transverso colon and sigmoid. He died two weeks later, and *post mortem* the growth was found to be of the cauliflower type, without the slightest tendency to surround the bowel, although it was of large size.

It is well known that attacks of diarrhoea occur in growths of the large bowel. Moynihan asserts that a growth of the right half of the colon causes diarrhoea, one of the left half constipation. My experience agrees with this statement, but I think the picture would be more complete to add that diarrhoea may occur in addition to the constipation when the growth is left-sided. The diarrhoea is much more upsetting to the patient than the constipation, which he is apt to lay little stress upon in recounting the history of his illness.

The pelvically situated tumours often give rise to another symptom—irritability of the bladder, so that prostatic disease is simulated. During the last three and a half years 28 patients suffering from carcinoma coli have been admitted to the surgical unit wards at St. Mary's Hospital. Of these 6 had urinary symptoms. At operation the growth in these patients is found to have formed adhesions with the bladder.

A bleeding from the rectum may come from a growth low down in the colon. Even should haemorrhoids be present, without a careful inquiry into the recent health of the patient the haemorrhage should not be attributed to them, for occasionally they themselves are due to a low growth blocking the venous channels above.

Clinically, then, cases of growths of the colon may be divided up into: (1) only vague abdominal symptoms, short-lived attacks of abdominal pain; (2) those obviously suffering from chronic obstruction; (3) cases of acute obstruction, the natural ending of groups (1) and (2); (4) those suffering from pronounced general symptoms with irregular temperature and very often diarrhoea.

X Rays in Diagnosis.

The value of x rays is very great. In every suspicious case a barium examination should be carried out. Radiographers are agreed now that the enema gives more information than the meal. But a warning must be given

against overestimating the reliability of the method. A growth may be present yet remain unrevealed. This is particularly the case when the growth is in the sigmoid colon, which lies folded up in the pelvis. The malignant stricture may easily lie concealed behind another part of the loop. Again, if the affected bowel lies with its axis in the direction of the rays, the defect in the shadow will not be seen. At the Portsmouth meeting of the British Medical Association in 1923 I showed the skiagrams of such a case.¹ They are not uncommon. Lockhart-Mummery² goes so far as to say that negative findings are useless, and A. F. Hurst at the same meeting said that he had met four cases where a growth was found, though an enema failed to show the slightest abnormality of the colon. The opposite error, the supposed demonstration of a growth which does not exist, is less common. At Portsmouth I called attention to such cases. I have met but three, in each of which a persistent spasm near the splenic flexure mimicked a growth (Fig. 1). Curiously, these patients on exploration had pelvic tumours, suggesting that the spasm above might be of a protective nature.

I would not like to over-emphasize the fallacies of x-ray examination. In many instances this method affords the best and clearest evidence of the existence of a growth at a time when removal is possible.

Sigmoidoscopy in Diagnosis.

When a growth can actually be seen through the sigmoidoscope, it is the best of all evidence of its existence. Sigmoidoscopy should therefore always be carried out. There exist, however, a number of cases where a growth low down in the sigmoid cannot be seen. This is because the tumour becomes fixed in the pelvis. Ever so lightly though it may be, it yet prevents the bowel from straightening out by air inflation, to allow of the passage of the instrument. The procedure has to be abandoned, but the very fact that this must happen is in itself suggestive.

The Occurrence of Multiple Growths.

The colon is one of the few places in the body where multiple malignant growths may be met with. The lower growths are generally supposed to be implantations from the primary orally situated one.

CASE IV.

I. S., a male aged 44, had a characteristic history of colonic growth. A faecal lump could be felt in the left iliac fossa, and, through the rectal wall, a small growth in the pelvis. At the operation a sigmoid growth was pulled up out of the pelvis for excision. Whilst doing this another growth was felt a little higher up. In all, four growths were discovered, the uppermost being just beyond the splenic flexure. A large excision was performed with good result.

The specimen, now in the St. Mary's Hospital Museum, is interesting in that all the tumours are of the same size. It is not possible to say which was primary.

CASE V.

W. W., a male aged 58, had a demonstrable growth in the sigmoid colon, both by rectal palpation and x rays. At operation the growth was excised and a caecostomy performed. He died a month afterwards. No faeces had passed per anum. Pus had discharged ind. *Post mortem* a leakage was found at the bscess spreading up to the region of the a large carcinoma of the ascending colon at operation. I had excised the implantation tumour.

FIG. 1.—Radiogram showing barium enema of a case where, even under pressure, the gruel could not be made to flow past the splenic flexure. There was no growth here. Obstruction due to spasm. At operation growth found in sigmoid flexure.

CASE VI.

F. B., a lady aged 63, had a caecostomy performed by her doctor for acute obstruction. After admission to hospital a growth was demonstrated by x rays at the lower end of the sigmoid. The caecostomy had nearly closed. Operation revealed a large growth fixed to the pelvis and irremovable. There was also a typical annular carcinoma of the transverse colon. This was removed by Paul's method and a permanent transverse colostomy left.

This last case, where the lower growth was so much the larger, leads one to speculate whether, by antiperistalsis, implantation orally cannot take place as well as caudalwards.

A Few Points in the Surgical Treatment.

The greatest decision which has to be made in every case is whether radical excision or a palliative drainage without or within the abdomen should be carried out. Hepatic metastases and peritoneal implantations, of course, negative any radical attempt. But local extension and the enlargement of near-by lymphatic glands stand in another category. A number of successful cases have been reported where a part of some neighbouring viscus has been removed and lasting cure resulted.

With regard to glandular enlargement, no information of any reliability at all is given as to the cause of the induration or increase in size by examination on the operating table, for infection from the ulcerated growth may be equally as responsible as carcinomatous invasion. Experience has shown that, in an otherwise suitable case, the carcinoma is often confined to the nearer enlarged lymphatic nodes. Thus we get the rule that it is sufficient to excise the affected region of the bowel with a moderate amount of the lymphatic drainage area.

The next great rule is that reconstitution of the continuity of the large bowel after excision of a growth should never be done in the presence of obstruction which cannot be relieved by enemata or aperients. This rule must be strictly adhered to, except sometimes when there is a growth of the caecum and an ileo-transverse colostomy is performed. The danger of leakage at the anastomotic junction in this case is very much less than when a union is made between two parts of the colon.

When such obstruction exists a two-stage operation becomes necessary: either drainage first and excision afterwards, or excision *plus* drainage first and reconstitution second. The most universal type of drainage operation is the caecostomy recommended by Sir Harold Stiles.³ This drainage operation has much to recommend it. Unless the tumour is in the ascending colon, the faecal fistula is away from the site of the subsequent operation, which can be performed through an uninfected region of the abdominal wall. On the other hand, when the growth is beyond the splenic flexure, a caecostomy does not always drain the bowel above the obstruction, so that conditions within the abdomen are not so favourable at the second operation. From this point of view a transverse colostomy is much more effective, but does not close as readily spontaneously. There are drawbacks whichever course is followed, and I am not prepared to lay down which is preferable at this stage of my experience; I have had good results from both methods. When a caecostomy has been made as a preliminary to a removal of a growth at the hepatic flexure, on the whole it is best to excise the caecostomy with the caecum, lower end of ileum and colon, to beyond the growth at the same time. This requires careful technique to minimize the soiling which must inevitably occur, but I think it best. In one patient I removed locally an hepatic flexure growth, performing an ileo-transverse colostomy, and leaving the caecum and lower distal end of the ileum to

drain through the caecostomy wound. The patient lived four and a half years before a recurrence caused his death, but the mucous fistula was rather a nuisance to him and the caecum prolapsed through the opening. In an old lady in whom I could only do a palliative ileo-transverse colostomy for a large hepatic flexure growth, I made a caecostomy to drain the secretion of the doubly excluded caecum; the same prolapse occurred. I was forced to remove the prolapsed portion under a local anaesthetic.

This brings me naturally to another very serious factor in all colectomies—namely, the gravity of infection from the bowel contents. Operations upon the stomach can be carried out and some soiling with gastric contents is harmless, but in colectomy it is necessary to take great precautions to diminish infection from this source. Death from peritonitis must be reckoned with as a result of the operation. Fortunately the resistance of these patients to infection from the bowel seems to be abnormally high.

As to the method of joining up the two ends of the bowel,

many surgeons now carry out an axial union. This seems to me the preferable way if a safe technique be adopted, for it allows a wider resection to be done and yet permits of suture without tension. Lockhart-Mummery asserts that after axial anastomosis leakage occurs because of the poor blood supply of the antimesenteric margin, which can be avoided by oblique section of the bowel ends. I have had the best results by performing an anastomosis by a method I described two years ago.⁴ The principle of this is to avoid the two non-peritonealized mesenteric angles from coming into apposition. It is here that union is likely to be imperfect, as all experiments on animals have shown,⁵ and it is an axiom in intestinal work that at least one surface of the viscus to be sutured should be covered with peritoneum. By slightly rotating the bowel ends before suture around their own longitudinal axes in opposite directions, peritoneum at least on one side of the suture

FIG. 2.—Axial union of the colon, showing how the posterior row of Lembert sutures is inserted after clamping the ends of the colon in such a way as to avoid bringing the mesenteric angles in apposition. The line of section after completion of the posterior part of the stitching is shown. Union is then effected by a through-and-through suture and an infolding Lembert suture in front.

line will be present all round the circumference. The method is shown in Fig. 2. In Figs. 3 and 4 are shown radiograms of a growth of the descending colon before and after excision by this technique.

Paul's method of excision, by which the growth is brought outside the abdomen, removed, and the two ends of bowel left to discharge on the surface, has fallen into disfavour with most surgeons, but I have found it to be an excellent method in properly selected cases. The operation can be done when acute obstruction is present, provided the distension of the bowel is not too great and the patient is equal to the prolongation of the operation beyond a simple drainage, which the greater intervention necessitates. The advantage is that the growth is removed at the earliest possible moment and the drainage is instituted at the best possible place, whilst there is no danger of intra-abdominal infection from leakage at a line of suture. After this operation, when the spur has been broken down by the use of a clamp, I find that closure can only be done satisfactorily by opening the peritoneum and withdrawing the adherent loop. I have not been able to close the fistula by the extraperitoneal method.

Growths at the lower end of the sigmoid are a difficult problem to deal with. Sometimes abdomino-perineal excision is the only possible operation. This is a formidable undertaking. When a short stump leading into the rectum can be retained, the method of Rutherford Morison is satisfactory. The growth is excised and the upper end of the bowel invaginated into the lower. The operation may present difficulties of access. The floor of the pelvis lies at the bottom

of a narrow cavity, and soiling is somewhat difficult to avoid. Nevertheless, most gratifying results can be obtained.

As to the most suitable incisions for these operations, it may be accepted that the paramedian is the best for growths in the transverse colon or sigmoid. For growths in the

FIG. 3.—Growth of descending colon, showing the defect in the shadow.

flexures or lateral parts of the colon the oblique incision, also advocated by Rutherford Morison, gives good access. It is much better than a vertical one through the outer part of the rectus sheath.

I have only spoken of radical extirpation of the growth. This is possible in a little more than one-third of the patients coming to St. Mary's Hospital. When the condition has advanced too far for excision, great relief may be afforded by relieving the obstruction, preferably by a short-circuit, perforce by an artificial anus. The rule about short-circuiting is that care should be taken not to exclude entirely the portion of the bowel between the ileocaecal valve and the growth. Such an isolated segment of the bowel will gradually dilate and ultimately burst.

The Results of Operative Treatment.

It is generally accepted that the surgery of cancer of the colon gives results better than those which can be obtained in some other regions of the body. Those who would like to know what can sometimes be effected in advanced cases should read Grey Turner's interesting book *Some Encouragements in Cancer Surgery*. Körte, in 1913,⁶ collected the records of 434 cases. Of these, 61.3 per cent. survived the operation and 38.3 per cent. lived over three years—that is, one-half of the survivors of the operation were in a fair way to being considered permanently cured. Paul⁷ reported 46.66 per cent. of three-year cures. R. T. Miller⁸ found that of those patients surviving excision 28 per cent. were alive after five years. But he points out that a considerable number of recurrences take place after the five-year period, so that the ultimate results must be less favourable. This is rather the impression I have got from my own cases. Kuttner⁹ gives the final results as only 10 to 12 per cent. cured, whilst Majerus¹⁰ reports that of 43 radical operations 8 patients were alive three years afterwards—that is, 18.6 per cent. Amongst his cases one recurrence took place at four years and one at eight, so that the final recovery figure would more nearly agree with that of Kuttner.

The early impressions obtained as to the success in surgery of cancer of the colon have to be modified somewhat in the light of further experience. But the answer as to whether surgery in this condition is justified is undeniably

that it is. Survival over three years is common, and up to five years not infrequent, and this in a disease which is quickly fatal once obstruction has come on. Many victims are at the time of life when they cannot expect to live for many years. They get immediate relief and prolongation

FIG. 4.—Radiogram taken seven months after removal of growth. Axial anastomosis by rotational method. Same case as Fig. 3. Note how mobilized splenic flexure has been lowered to effect the junction.

of life in comfort. Gloomy as the outlook of a carcinomatous patient is, when the disease attacks the colon there is indeed hope in surgery.

SAVE THE WOMEN AND CHILDREN.*

BY

COMYNS BERKELEY, M.D., M.C.CANTAB.,
F.R.C.P.,

OBSTETRIC AND GYNAECOLOGICAL SURGEON, THE MIDDLESEX HOSPITAL;
PRESIDENT OF THE METROPOLITAN COUNTIES BRANCH.

FROM time immemorial it has been the proud tradition of Englishmen, wheresoever scattered over the face of land or water—in the presence of danger, to rally to the cry, "Save the women and children." Such a cry has become part of our common language. Let it be the slogan of the medical profession.

Every year some 700,000 women in this country pass through the pangs of labour, and of these 3,000 never leave their beds again except in a coffin. Such is the appalling sacrifice made by our women in the performance of a physiological act, and in that of the primary object of their sex—the provision of healthy citizens for our nation. Most of these women were in good health up to the time of their pregnancy or confinement; most of them were young and had very many years of active and useful life before them.

Since 1900 the infant mortality, after the first month, has fallen from 154 to 69 per 1,000 live births. The general death rate of all persons at all ages has fallen. The death rate from all causes of women from 15 to 45 has fallen, but the maternal mortality, and the infant mortality at birth

* The substance of an address to the Metropolitan Counties Branch and to the West Dorset Division of the British Medical Association.

and during the first month of life, would appear to have remained stationary. During the last twenty years the maternal mortality has kept at about 4 per 1,000 births. The prospective mother, therefore, is seriously handicapped in comparison with other members of the community.

If we examine certain tables in the Registrar-General's report dealing with the causes of death we find those due to the results of child-bearing come third on the list; and if we examine the table dealing with the causes of death during pregnancy, labour, and the puerperium we find that sepsis comes first, toxæmia second, and hæmorrhage third, and that these three account for the very great proportion of lives lost. In other words, most of the women who died last year as a result of child-bearing ought to be alive to-day. If 3,000 women died, how many, escaping with their lives, had their health ruined, were rendered sterile, or suffer from some other disability? How many of them will have to submit to some operation, with a certain percentage of deaths? In the case of the children also, how many of those who survive their birth are during its process injured for life? Apart from such a mortality, there is every year added to the community a vast number of women who have to bear the burden of ill health and suffering, and numbers of unsatisfactory children who, instead of being an asset to the nation, will be a source of nothing but trouble and expense. Truly the slogan of the medical profession should be "Save the women and children."

Such a serious maternal and infantile mortality must be prevented. The Bible teaches us that we should be importunate, and it is only by all of us, in season and out of season, preaching the doctrine that these lives should be saved that, in the end, they will be saved.

I will deal with this subject under four headings: (1) Educational, (2) Ante-natal, (3) Intra-natal, (4) Post-natal.

EDUCATIONAL.

The medical student, the pupil midwife, the medical man, and the laity all have to be educated in the subject under discussion. A medical student in the past was badly educated in the subjects of midwifery and gynaecology. The amount of time he was required to give to the study of midwifery was deplorably short of what it should have been. That the teachers are not entirely at fault is obvious, since they have not had the facilities to teach midwifery and gynaecology. The responsibility for this inefficient teaching in the past must rest with the various examining bodies, who have had it in their power to prescribe what rules and regulations they deem right. Medical men in the higher ranks of the profession have failed, until recent times at any rate, to realize that the science and practice of midwifery is as important to the general community as that of medicine and surgery, and as a fact even more so. This is reflected in the regulations of the Royal Colleges, which do not insist that there shall be a definite proportion of medical men familiar with the teaching and practice of obstetrics on their councils.

The majority of students when they go into practice are not going to operate, and yet before they can sit for their final examination in surgery they have to spend three months in the out-patient and six months in the in-patient surgical department. The majority of students are, however, going to practise midwifery. The General Medical Council has made a regulation that after January 1st, 1923, a student must have obstetric and gynaecological experience in the wards, must be signed up as having attended regularly all the departments of the maternity and gynaecological units for three months, and must have attended five labours conducted by a teacher or member of the staff of a lying-in hospital or of the maternity department of a general hospital before attending the remaining fifteen. This wise action of the General Medical Council will, I am sure, lead to a great improvement in the practice of midwifery, because the future practitioner will be taught by this experience to realize within what limits normality lies. He will thus be able to diagnose better impending or present dangers and difficulties, and he will, moreover, not be tempted to interfere when he should hold his hand. The medical student is allowed by the Conjoint Board to sit for his examination in midwifery a year before his final examinations in medicine and surgery. This has led to

generations of students regarding midwifery and gynaecology as unimportant subjects from an examination point of view. Moreover, however willing a teacher may be to instruct his students, he has not had the proper facilities. More maternity beds are required, either in the general or lying-in hospitals.

There is a great danger of pushing the scientific education of the average student too far. Our students have now so many subjects to master that they are apt to forget that there are such things as wards with patients in them. What the student requires is more practical teaching at the bedside, at any rate in midwifery. He should be able to diagnose most of the emergencies of pregnancy and labour just as easily as he is taught to diagnose most of the medical and surgical emergencies.

Then the education of pupil midwives is still far from satisfactory. How important it is that the midwife should be well educated is, I think, shown by the fact that some 70 per cent. of the pregnant women are attended by midwives. There should be more post-graduate courses for midwives. All local authorities would be wise in encouraging the midwives practising in their districts to attend such courses, and should give grants for the purpose.

The education of the laity is already taking place through the medium of various voluntary societies dealing with mothercraft and infant welfare. The approved societies are bestirring themselves, and, more and more, married women are getting to know about ante-natal supervision, and to expect it.

ANTE-NATAL.

Labour, which is a physiological act, just as much as defaecation and micturition, in the vast majority of women only becomes pathological when they have been deprived, by their attendant or because of their own carelessness or ignorance, of ante-natal supervision. Medical students and pupil midwives should be taught that pregnancy is for women a normal state of health, but that since she is harbouring a child her metabolic functions may be stressed, and so she requires careful supervision.

Ante-natal supervision and treatment can abolish all the catastrophes of contracted pelvis; it can, by reducing the number of difficult labours, minimize the dangers of manipulation and infection. It is fair to say that it can practically abolish eclampsia. It can in many cases prevent women, the subjects of organic disease, such as that of the heart and kidneys, from being worse as the result of their pregnancy. It can ensure a greater percentage of births of live and healthy children. It can prevent an enormous amount of suffering and disability and many deaths which are attributable to childbirth. In the report of the Scottish Departmental Committee it is stated that in the histories of 10,000 gynaecological cases it examined, 2,800 had relation to previous pregnancies and labours.

By ante-natal supervision such conditions of local infection as oral and nasal sepsis, sores and boils can be treated, themselves undoubtedly in many cases the source of puerperal sepsis. And yet the majority of pregnant women in our country have no ante-natal supervision of any kind. Nevertheless, the public is getting to know more and more concerning the benefits of ante-natal treatment. After all, ante-natal supervision is a very real aspect of public health. Medical students should spend at least three months studying the normal pregnant woman, so that when they go into practice they may be able to detect, early in labour, any sign of abnormality. It is because, in the past, the average medical student has not been sufficiently grounded in the normal results of impregnation that he fails, when he goes into practice, to realize as well as he should what may be left to Nature, and in what circumstances he should lend her his assistance. As a result he may be tempted to interfere with Nature when he should not, and so we have, perhaps one reason why the maternal and infantile mortality and morbidity would appear to have remained stationary during the past twenty years.

Next we come to pupil midwives. The Central Midwives Board by its latest regulations proposes, as far as it can, to remedy the lack of ante-natal training by stipulating that these pupils shall have more ante-natal experience. Midwives must be taught to insist, as far as they are able, that

all their patients should have ante-natal supervision, either at an ante-natal centre or by a doctor.

Lastly, as to the role of the laity in regard to ante-natal treatment. By propaganda pregnant women must be taught that such supervision is not only imperative but their right. The medical profession must never cease its efforts until every pregnant woman realizes the importance of such supervision. There are so many ante-natal centres now that most women, when they cannot afford to pay a doctor his fee, can obtain free advice. The officers in charge of such centres should communicate, when necessary, with the doctor or midwife who is going to attend the patient. At present this practice, I am afraid, is not followed nearly as often as it should be.

Research work in the physiology and pathology of child-bearing should be encouraged in every way possible by grants from the Ministry of Health and other authorities; but if pregnant women do not take advantage or are not persuaded to take advantage of ante-natal supervision, of what use is this research work? We cannot compel all pregnant women to submit to ante-natal supervision, human nature being what it is. Can we persuade the majority of women to do so? I have given much thought to this question, and it seems to me that the majority of pregnant women may practically be persuaded to do so. If the payment of the maternity benefit was made conditional on the woman presenting a certificate to the effect that she had attended an ante-natal centre, or had been examined by a medical practitioner, during at least the last month of pregnancy, I am certain that the present maternal and infantile mortality and morbidity would be appreciably diminished. The highest maternal and infantile mortality rates in England and Wales are found in districts in which there is least ante-natal supervision.

Ante-natal supervision must include not only attention to the health of the individual, not only the detection of abnormalities which for the moment do not trouble her, such as a contracted pelvis or malposition of the child, but an inspection of the home in which the confinement is to take place. For though an environment of dirt and squalidness is not such a menace to normal labour as we might suppose, yet if the labour should chance to be abnormal then the scales of recovery are heavily weighted against the woman. Especially is ante-natal supervision important to primigravidae. Apart from the fact that none of them have had a trial labour, and the attendant, therefore, has no previous history as a guide, eclampsia, the evidence of which can be detected by an examination of the urine and certain premonitory signs, occurs 70 times out of 100 cases in first pregnancies, and has a death rate of 23 per cent. in women and 50 per cent. in the infants. I take it that all medical practitioners to-day are in full accord as to the value of ante-natal supervision—nay, as to its absolute necessity. Some of them, nevertheless, are perhaps not so whole-hearted on this question as others, because in their own particular environments the provision of such a protection for every pregnant woman, or even for the majority of pregnant women, seems hopeless. I would like, however, to stress this aspect of the case. If ante-natal supervision is neglected by the general practitioner, it will certainly not be by the Ministry of Health, the medical officers of health, or by the ante-natal clinics. It is up to the family doctor to see that this essential part of his family work is not taken out of his hands. None can help him in this respect except the Almighty, who, as we have been taught from our childhood, is prepared to help those who help themselves.

NATAL.

What relation have the circumstances attending the birth of the child with the subject we are discussing? The environment of the patient may not be of such importance as, on the face of it, one would expect. Some of the worst cases of puerperal sepsis occur in women who have never been submitted to an internal or any other examination. It is true that large numbers of women pass through a normal puerperium in spite of much and repeated manipulation at their confinement. But these facts cannot be taken to indicate, as many would have us believe, that the environment of the patient is of not much importance, that puerperal sepsis is mostly autogenous, and that the

best thing for the woman and child is to terminate labour as quickly as possible after the first stage by the use of the forceps and by the untimely expression of the after-birth. Experience and statistics, which, as Moynihan has remarked, sometimes tell the truth, prove entirely the contrary.

It is possible that women whose normal habitat is that of dirt and neglect are more immune to the invasion of the bacteria of puerperal sepsis, and as the majority of labours are normal, and attended by midwives, the incidence of puerperal sepsis in their case is not so great. But supposing such women are subjected to operative measures, then the results, if they could be collected, would be infinitely worse than those following such operative measures in more favourable surroundings. There can be no better indication of the great necessity for more maternity beds. A doctor when he has a poor patient suffering from some severe medical or surgical complaint is able to send her at once into a hospital or infirmary. But not by any means can he do so in the case of a woman in difficult labour. He may try to get her into hospital, but there may be no maternity beds available, and he has to proceed to operate upon the patient. It may be impossible for him to obtain proper assistance. He cannot obtain a sterilized outfit unless he provides such himself. Moreover, in better surroundings the doctor has, in many cases, the relatives to contend with. In what other condition necessitating medical or surgical treatment is a doctor expected to exercise so much skill or devote so much time for such an inadequate fee? The public must be educated in this respect.

The remedies for this state of affairs are more maternity beds; the provision by the local authorities of sterilized outfits for labour, the setting up in each district of a panel of medical men, to be paid by the local authority if the patient cannot pay, who have had special experience in midwifery practice and upon whom the doctor can call for assistance if he wishes. Even if the local authority has not the funds for such assistance, as a commercial proposition such a panel should appeal to the approved societies.

Although it is true that some of the worst cases of puerperal sepsis are autogenous, it was proved conclusively that 75 per cent. of the cases of sepsis dealt with at the British Congress of Obstetrics and Gynaecology held in London in April, 1925, were associated with repeated internal examinations, and injuries resulting from operative midwifery. And what about the after-results? Men in charge of gynaecological departments can answer this question.

POST-NATAL.

From the post-natal point of view the question must be studied in two aspects—the immediate and the remote. It is an acknowledged fact that a large percentage of the diseases peculiar to women, resulting in a certain number of deaths and a great amount of suffering and disability, owe their origin to the fact that the patient has given birth to a child. It is deplorable to think that the results of a physiological act should in so many instances result in some pathological condition; that a woman who does her duty by providing citizens for the nation should be thus handicapped, as against one unwilling to do her duty. Think of the number of women whose health is ruined for life as a result of child-bearing. In the year 1920, 5,413 women died, and six out of seven who died under the age of 35 in the United Kingdom died from causes incidental to child-bearing.

And, lastly, as to the immediate post-natal supervision and treatment. This is the most difficult question of all, and, in a way, the most important, since the medical profession is nowadays entirely in accord with the importance of medical education, ante-natal supervision, and intra-natal care. It is when we come to discuss the disease of the immediate post-natal state that the difficulties arise which are, to many men, insuperable or apparently insuperable. Of all the deaths attributable to childbirth, puerperal sepsis claims by far the largest number of victims. As someone has remarked, there are two things known for certain about puerperal sepsis: one is nothing, and the other is that the medical attendant will be blamed. There is a certain amount of truth in this statement. The

bacteriology up to a point is known; the streptococcus is practically in all cases the *fons et origo*, but it may be that there is a special variety of streptococcus peculiar to puerperal sepsis. What do we know about the predisposing causes of puerperal sepsis; of the immunity of the normal pregnant woman; of how to assist this immunity; of how to recognize if this immunity is failing? What increases the virulence of the organism which has been lying harmless on the vulva or in the vagina of a woman up to the time she gives birth to a child? Why does a method of treatment appear to be specific in one case and absolutely useless in another? We cannot answer these questions. Reports which are issued from time to time leave no doubt in the mind of the reader that puerperal sepsis is frequently due to lack of ante-natal supervision, to faulty technique at the time of the confinement, or to careless nursing. But, after all, such reports deal with comparatively few cases. Granted that in the cases dealt with such a conclusion is justified; some men never wear gloves, never trouble about or cannot obtain sterilized outfits, have a large percentage of operative midwifery in their practice, and yet from their statements do not appear to get more puerperal sepsis than their very careful fellow practitioners. No one would be rash enough to contradict the statement that the more care that is taken the less likelihood there is of infection.

The plague of puerperal sepsis must be dealt with here and now. The Divisions of the British Medical Association should hold meetings and discuss the question, and the Divisions should appoint representatives to attend a joint meeting of the Association further to discuss the question. Research work should be organized by some competent authority; and here I think perhaps the crux of the whole question lies. Any man, or body of men, engaged in research must have all the information it is possible to obtain. Much of this information can only be obtained by a new and thorough system of notification. The present state of notification is absolutely hopeless. Fothergill collected the statistics of notification in 204 areas. In 93 of these areas the total deaths from puerperal sepsis were more than the total notifications of puerperal sepsis. He also reckoned that in these 204 areas there should have been thirty times as many notifications as deaths. There were only twice as many.

There are many reasons why at present notification is in such a hopeless state. The term "puerperal fever" required by the notification is one that makes many practitioners hesitate to notify, so are those of "puerperal sepsis" and "puerperal pyrexia." Such terms to the lay mind are apt to convey the impression that the illness is due to the doctor or midwife. It takes a lot of courage to make such a notification. The relatives know of it, the medical officer of health knows, and he, indeed, may be practising in the same neighbourhood. In many cases the man is apt for these reasons to attribute the rise of temperature to influenza, constipation, and so forth. A vast number of cases are only mild in nature, and the medical attendant persuades himself that his diagnosis was correct, and that the patient never had puerperal fever. As long as puerperal fever is considered by the laity to be due to bad midwifery, notification will remain a farce. Again, there never has been, perhaps there cannot be, any exact definition of what is really included in the terms "puerperal fever" or "puerperal sepsis." Many a general practitioner does not know whether he should notify a particular case or not. Doctors do not hesitate to notify tubercle, small-pox, scarlet fever, measles, and so on; they know they will not be blamed.

And then, what good comes of notification except for statistical purposes? In the case of the midwife, it is true that she is carefully supervised and has to conform to certain regulations of the Central Midwives Board which deal with the preventive treatment for other patients; but the medical profession is not concerned in these. If a doctor notifies a case of puerperal fever, does he by right obtain any assistance? None whatever. All his report does is to swell the statistics of the medical officer of health.

A new definition is required for purposes of notification. What is required is a term comprising a state of the patient, quite easily diagnosed, and one which practitioners will be willing and ready to notify, and which can be notified

at once, irrespective of whether it is due to sepsis or not. Such a term as "fever during the puerperium" might fill the bill. As it includes any febrile condition occurring in a puerperal woman, and does not involve any theory as to its cause, it would not arouse any suspicion of incompetence in the attendant, and would not necessitate any delay until a complete diagnosis could be made. It is most important that cases of puerperal fever should be identified at the earliest possible moment if the patient is to have the best chance, and the diagnosis is often most difficult in the early stages. Moreover, an early diagnosis means less danger of the disease being communicated to others. The doctor is often called in too late. There would be no need to make a diagnosis of puerperal fever or of any other disease, but simply to notify the case if the temperature was 100.4° or over for more than twenty-four hours.

A large number of the infections in puerperal fever are of a mild nature; yet very many of these mild infections are followed by ill health and sterility, which might have been prevented if appropriate advice and treatment could have been obtained. Also, such mild cases have a danger peculiarly their own, since infection of other patients is perhaps more likely to occur, and it is known that the virulence of an organism may be very greatly enhanced by transplantation from one patient to another. If a medical practitioner could notify without running the risk of blame, and if, having notified, he could obtain appropriate help, then notification would not be the farce it is to-day. Such a notification as I suggest would mean more clerical work for the practitioner, and many objections could be advanced against it. But the advantages that would accrue to him personally, and the immense advantage that would accrue to the community as a whole, would outweigh all the disadvantages. Naturally he would be paid for the certificate. He should then have at his disposal the services of an expert opinion, of a bacteriologist, and of a bed in a hospital or infirmary to which, if he liked, he could send his patient; or if not, then he should have the services of an anaesthetist and a trained nurse. Cases of puerperal sepsis require nursing of the highest standard. How often do they get it? How often does the general practitioner have both to give the anaesthetic and perform the operation? In each district there should be a panel of doctors who have special knowledge of midwifery, and who could be called upon to assist or give advice in any case. There should also be a panel of trained nurses.

The question of more beds is a very important one. The Ministry of Health favours the establishment of small maternity homes in which the local practitioners can attend their patients. Such homes are very desirable for normal cases, especially for patients whose surroundings are unfavourable. But something more than this is wanted. There should be beds especially for difficult labour and sepsis in the puerperium, and these beds should be under the charge of experts in midwifery. All this would cost a lot of money, but, money or no money, something drastic has got to be done in the near future; and it is more than likely that the approved societies would find that helping to finance such a service would save them a large sum of money. It is true that the practitioner might object to sending in his reports to a local medical officer of health, who might be a neighbouring practitioner. He might be afraid of the patient getting hold of his report and suing him for negligence. But such difficulties can be overcome. He could notify the temperature to, and, if necessary, request assistance from, the county medical officer of health, while the consultant who is called in could make the report on the case and forward it direct to the Research Committee.

The medical press has lately been the seat of a somewhat acrimonious discussion concerning the responsibility, if any, of the medical profession with respect to puerperal fever. It is no use our sitting down and accusing one another of this and of that. We must all of us, experts and general practitioners, join together and work harmoniously in a great endeavour to improve matters. Is it likely that we shall obtain any advantages from such disputations? On the contrary, the medical profession, unless it is careful and wide awake, may find itself in the cart, to use a modern expression, with respect to the measures which may be

insisted upon by the Government in an attempt to limit the incidence of puerperal sepsis.

It is obvious from the writings and speeches of public health officials, as also from those of the laity, either personally or combined in the form of the approved societies, that a great movement is taking place to insist that the present deplorable maternal and infantile mortality and morbidity ought to be, and shall be, diminished. If, therefore, the medical profession itself does not take up the question seriously and now, it will wake up one morning to find that all kinds of rules and regulations have been made that may seriously affect its position. Let us all do our best; it is no use cursing each other; this will not improve matters; this will not save a single life. The general practitioner, apart from the patient, is the most seriously concerned. By insisting on ante-natal supervision, by linking up with the county health authorities, by welcoming the assistance of obstetric experts, bacteriologists, trained nurses, and voluntary societies, by reporting at once cases of fever during the puerperium, by giving willingly all the information he can to those constituted to receive it, the general practitioner is bound to be the chief instrument in the reduction of the maternal and infantile mortality and morbidity.

THE IDENTIFICATION OF FIREARMS AND PROJECTILES

AS ILLUSTRATED BY THE CASE OF THE MURDER OF
SIR LEE STACK PASHA.

BY

SYDNEY SMITH, M.D., D.P.H.,

PRINCIPAL MEDICO-LEGAL EXPERT, EGYPTIAN GOVERNMENT SERVICE.

(With Special Plate.)

On November 19th, 1924, Sir Lee Stack Pasha, the Governor-General of the Sudan and Sirdar of the Egyptian Army, was shot while returning from the War Office in Cairo about 1.30 p.m., and died on the following day. His aide-de-camp, his chauffeur, and a native policeman were wounded, but recovered.

This was the culminating point of a series of political crimes which, commencing with the attempted murder of Captain Combe in November, 1919, accounted for thirty attempts at murder, of which twelve were successful. Of these, seven took place in November-December, 1919, seven in 1920, two in 1921, and thirteen in 1922. If we exclude the attempt on Mr. Amber in February, 1923, and the stabbing affair at Heliopolis in the same year, the political significance of which is doubtful, no further cases of political murder occurred until the Sirdar case in November, 1924.

The action taken by the British Government and the political effect of this outrage are foreign to the purpose of this article, and I shall confine myself to the study of the crime from its medico-legal aspect, to the exclusion of all other considerations.

The Sirdar died on November 20th, and a necropsy was performed the next day, when the following injuries were found:

1. A wound of the left hand from a bullet which entered on the internal aspect at the base of the little finger and made its exit on the back of the hand at the base of the fourth metacarpal bone.
2. A wound of the left foot from a bullet which entered in the middle of the sole and passed to the outer side of the foot below the ankle, from which position it was extracted before death.
3. A wound caused by the entrance of a bullet on the outer side of the right pelvic bone just below its crest. The bullet passed upwards and inwards through the muscles of the abdominal wall to the level of the right lower ribs. It was slightly deflected to the left at this point, entered the abdominal cavity, and passed through the gall bladder and liver. It made its exit on the left upper diaphragmatic surface of this organ, causing a ruptured wound $1\frac{1}{2}$ inches long. It continued its course through the diaphragm, entered the chest at the level of the xiphisternum, and was found in the tissues of the anterior mediastinum under cover of the fifth left costal cartilage and immediately above the heart. There was no damage to the stomach or intestines or any haemorrhage within the peritoneal cavity.

The bullet extracted from the body was a 0.32 automatic bullet, the tip of which had been cut in a cross-shaped manner with the object of converting it into a "dum-dum" or expanding bullet. Death was due to shock and haemorrhage, the direct result of the bullet wound of the abdomen.

The aide-de-camp, Captain Campbell, received a bullet wound in the right side of the chest, probably from the same bullet which struck the Sirdar's hand. The chauffeur, March, received a bullet wound of the right leg just above the knee, and a native policeman received a bullet wound of the right hip region. An examination of the car showed that it had been struck five times on the right side, the direction of fire being from before backwards.

The reconstruction of the crime from the above information is not difficult. The assailants were waiting on the right side of the road and began to fire just before the car reached them; the first shot probably passed through the forward door of the car and entered the chauffeur's leg, passing upwards towards the thigh. The next shot probably struck the Sirdar's hand, smashed the stick that he was holding, and was deflected into Campbell's chest. The latter then in all probability pulled the Sirdar down into the body of the car, and as he did so the Sirdar's foot was raised as he overbalanced and a bullet was received in the sole. Finally, while in this position another shot was fired at him, striking him in the right hip and passing across his abdomen to the left side of the chest.

MATERIAL OBTAINED FOR INVESTIGATION.

Nine empty cartridge cases were found at the scene of the crime. These were all 0.32 inch automatic pistol ammunition, and from an examination of the extractor and other marks it was shown that three different types of automatic pistols had been used.

Six bullets were obtained from various victims; all of these were 0.32 inch automatic pistol ammunition with a heavy cupro-nickel jacket. Five of them had a cross-shaped incision in the tip to convert them into expanding bullets.

An examination of the projectiles showed that at least three different types of weapon had been used—namely, (1) a weapon of the Colt type with six left-handed rifling grooves, (2) a weapon of the Browning type with six right-handed grooves, and (3) a weapon of the Mauser type with four right-handed grooves.

Wholesale arrests followed the crime, and though certain of the actual murderers were arrested not a shred of evidence was obtained, in spite of all the efforts of the investigating authority. Fortunately a native named Helbawi, who had served a term of penal servitude for a previous attempt on the life of Sultan Hussein, was liberated from prison about this time, and decided to turn secret agent. With his history he had no difficulty in getting into contact with the suspects, and soon learned that two of the gang were young students named Enayat. From his knowledge of the psychology of the native he advised that the best plan to follow was to frighten these young men into flight, and to suggest that they should make for Tripoli. The object in suggesting Tripoli was to have them arrested in territory under the Frontier Districts administration, where they could be held without the formalities required in the other parts of Egypt. He believed that in these circumstances the younger Enayat could be induced to confess and thus implicate other members of the gang.

Helbawi was successful in his efforts, and managed to scare the Enayats into flight. They were arrested on the train while making for the frontier, and with them were secured four automatic pistols and a quantity of ammunition; these were forwarded to my department for examination in order to ascertain if any of them had been used in the crime.

Examination of Material.

The weapons were of the following brands and calibre:

- 1 Colt automatic pistol 0.32 inch.
- 1 Süreté automatic pistol 0.32 inch.
- 1 Mauser automatic pistol 0.25 inch.
- 1 Libia automatic pistol 0.25 inch.

The barrels of the weapons were first examined chemically and found to be free from the decomposition products of

FIG. 2.—A, Cartridge case found at the scene of the crime (same as in Fig. 1). B, Cartridge case fired from the Sûreté pistol. Note the eccentric position of the depression in the cap in both cases (1, 1), the position and nature of the depression in the cap in depression in cap caused by breech block (2, 2), and the circular depression in cap caused by breech block (3, 3).

FIG. 3.—A, Cartridge case found at the scene of the crime. B, Cartridge case fired from the Colt pistol. The characters of the extraction marks (indicated by arrowheads) are identical.

FIG. 4.—A, Cartridge case found at the scene of the crime. B, Cartridge case fired from the Sûreté pistol. The scratches (1, 2, 3, 4) on the surface of the two cartridge cases are identical.

FIG. 5.—The bullet taken from the foot of the Sirdar.

FIG. 6.—Cast of rifling marks from the bullet taken from the foot of the Sûreté (above) and from a bullet fired from the Sûreté pistol (below).

SYDNEY SMITH: IDENTIFICATION OF FIREARMS AND PROJECTILES.

THE BRITISH
MEDICAL JOURNAL

FIG. 8.—A, Bullet seized in the
B, Bullet from the victim. (Side view.)
The manner in which the nicked jacket has
been incised is the same in both bullets.

FIG. 6 AND 7.—Comparison of a bullet fired from the Colt pistol
with the bullet which caused the death of the Sirdar. Arrowheads
point to vertical scratch groove caused by a fault in the barrel
of the pistol. The ordinary rifling grooves cannot be seen.

Colt bullet.

FIG. 9.—Lower part of door taken from the house of Mahommed Lucifid. The lower panel has been removed and the four seized pistols placed
in the secret cavity. Note the worn appearance of the nail holes, showing that the panel has been frequently removed and replaced. The
nails of two of these pistols caused depressions in the wood as described in the text.

powder. All four were clean, well oiled, and well cared for, but the Sûreté pistol had a trace of rust at the muzzle which might be expected to obscure the identification marks on bullets fired through it. The empty cartridge cases found at the scene of the crime and the bullets extracted from the various victims had now to be compared with cases and bullets fired from the seized pistols.

NATURE OF THE INVESTIGATION.

Before proceeding to the actual comparison it may be as well to indicate briefly the nature of the investigation.

When an automatic pistol is fired the empty case is automatically thrown out of the chamber and a new cartridge slides forward into its place. In this automatic charging and ejection of the cartridge several things happen which leave their imprint on the cartridge case. The cartridge is forced up the magazine, its nose is directed towards the chamber by means of metallic guides, the breech-block strikes the base and forces it into the firing chamber. The firing-pin strikes the cap, and on the explosion taking place the breech-block moves backwards by gas pressure, the extractor hook catches the rim of the cartridge case, and it is pulled backwards with the sliding mechanism until it reaches a bar of metal jutting from the side of the slide. The cartridge case strikes this bar on the side opposite to the extractor hook, and as the hook continues its backward pull the case is thrown out. This occurs with a considerable amount of violence, and we may expect to find certain marks on the cartridge case from each operation, the extent of the marks depending on the violence of the operation. The empty case is therefore examined in detail under a low-power microscope or with a watchmaker's eyeglass for any marks which may have resulted from these operations. On the surface there may be cuts or scratches caused by irregularities in the breech or in the slide: these may be absolutely characteristic and imprinted on every cartridge, and when found may prove that the cartridge case was used in a certain weapon.

The mark of the extractor hook on the edge of the cartridge must be looked for. This varies considerably in cases fired consecutively from the same weapon, in depth, length, etc., but if a number of cartridges are fired the characteristic marks will become obvious. The surface of the base must be examined for the mark of the ejector bar, which often leaves a most characteristic depression. Finally, the position of the depression in the cap, whether central or to one side, and the character and depth of the depression, must be noted.

When a weapon is seized it has to be decided whether the empty cases were fired from that particular weapon. After the preliminary examination already described a number of rounds are fired from the pistol, using several different brands of ammunition, including, if possible, several cartridges of the same make as the ones found. The weapon is fired into a roll of cotton-wool or rags (backed by a sandbag), the object being to obtain the bullets for comparison without distorting them, as well as the cartridge cases. The empty cases are collected and examined in detail as outlined above to observe whether any particular mark found on the seized case is reproduced on the fired cases.

The cartridges may be marked in such a characteristic manner that there can be no doubt of their identical origin, as in Figs. 1 and 2, in which there are scratches on the case of a particular kind, a definite extractor mark on the rim, and a firing-pin which strikes to one side. In other cases the marks may be absolutely different, and at once prove non-identity. A great many cases occur, however, in which the marks are ill defined and the matter becomes more difficult. In numbers of instances the marks from cases fired consecutively through the same pistol have no resemblance whatever, simply because they are ill defined; they are, however, in the same position on the cartridge, and this must always lead the observer to make further experiments and obtain new samples.

It is never safe to say that a cartridge case was not fired from a given pistol unless the marks are quite different, and a case which bears no marks at all may quite well have been fired from the same pistol as one which leaves well defined marks. In general, however, though it is unlikely that all marks will be equally good, it is usually possible to obtain definite information from the marks of the firing-pin, extractor,

ejector, or breech-block on the base or rim, or from grooves or scratches on the surface. In weapons of the same manufacture the marks are of the same general nature, but in every weapon there are individual differences which enable it to be definitely identified in the usual case.

The cartridge cases having been examined, it is necessary to make a close comparison of bullets fired from the seized weapon with those found in connexion with the crime. It is as well to fire half a dozen rounds from the weapon before it is cleaned. It is then cleaned and a further series of rounds fired, using if possible similar makes of cartridges and others of different make. The bullets are then collected, labelled, and examined in detail. The weight, length, and diameter are ascertained. The projectile is then fixed in some sort of an instrument which enables one to examine its surface under a low power, and at the same time to turn it round.

On every bullet fired from a pistol or revolver there will be found certain marks. The most prominent of these consist of a series of grooves, sloping either to right or left, which are caused by the lands in the barrel of the weapon. The number and direction of these grooves are first noted, the pitch is then ascertained, and the width of each groove and space between the grooves. In between the grooves and at different parts of the surface of a fired bullet there are found marks and scratches of various kinds. Some of these are caused by slight faults or patches of rust in the barrel, others are caused by metallic fouling. The former are constant, the latter vary from shot to shot. Each individual groove and space between grooves is now minutely examined under the microscope for some individuality. It is obvious that in weapons of the same manufacture the number, direction, width, depth, and pitch of the grooves will be the same, but in every weapon certain individual differences are usually to be found in one or more grooves. There may also be definite characteristic marks between the grooves.

It should also be clearly understood that a slight difference in calibre of the bullet and a difference in the charge of powder may make a considerable difference in the markings. If the diameter is slightly altered the smaller bullet passes through the barrel without definite grooves being cut into the surface, and even when bullets on measurement appear to be of the same diameter one will frequently be better marked than another.

RESULTS OF THE INVESTIGATION.

Having now outlined the method of procedure, let us compare the cartridge cases and bullets found in the Sirdar case with cases and bullets fired from the pistols seized with the Enayats accused of the crime.

As no 0.25 inch bullets or cases were found at the scene of the crime, attention may be confined to the Colt and Sûreté pistols, for they are of the same calibre as the ones used in the crime.

Empty Cartridge Cases.

(A) Three of the empty cartridge cases discovered at the scene of the crime were found to be marked by a series of scratches on the surface, the ejector bar had caused a deep nick in the edge of the base, the firing-pin had struck towards the side of the cap, and the breech-block had caused certain curved marks on the smooth surface of the cap. Cartridges fired from the Sûreté pistol showed an exactly similar condition, every one of these characteristic marks being produced on every case fired from this pistol. Figs. 1 and 2 show these in detail and leave not the slightest doubt that this Sûreté pistol and no other was the one from which three of the shots were fired.

(B) Three other cases bore extractor and ejector marks characteristic of a Colt pistol. These were compared with a series of shells fired from the seized Colt and were found to be identical. Fig. 3 shows the mark of the extractor hook in both cases. All Colt pistols cause a somewhat similar mark by the extractor hook, but in each case there are slight differences. In this instance twenty-four Colt pistols were used as controls, and in no instance was an exactly similar extractor mark produced.

Bullets.

(A) The Sûreté pistol was rifled with six lands with a right-handed twist, and bullets fired through it show six well

marked right-handed grooves with a considerable degree of scratching between them. The bullet taken from the foot of the Sirdar had six well marked right-handed grooves of identical width and pitch, but with much less scratching between them (Fig. 4). Fig. 5 shows a plasticene plate on which the rifling marks of both specimens have been impressed. For comparison the plates have been superimposed and the identical nature of the grooves becomes at once apparent. However, in view of the lack of any characteristic fault or detail, I considered it unjustifiable to give a decided opinion on the matter, although there was obviously the strongest suspicion that the bullet had been fired from this pistol.

(B) The Colt pistol was rifled with six lands with a left-handed twist, but the barrel was in a bad state and the lands worn so that bullets fired through it did not show clearly marked grooves. It had, however, a fault in the muzzle end of the barrel which produced a scratched groove in every bullet fired through it. This lay between two of the normal grooves and was broader than those grooves. On comparison with the bullet taken from the chest of the Sirdar the same peculiarity of marking was found, and on minute examination of the two bullets the details of marking were found to be identical (Figs. 6 and 7). It could be stated with absolute certainty that the bullet from the chest of the Sirdar had been fired from the Colt pistol.

Tips of Bullets.—A comparison of the tips of the bullets seized with the Enayats with those extracted from the victims showed that the method of cutting the tips was identical. In each case the tip showed a saw cut which penetrated into the lead and a file cut above which increased the width of the saw cut. Fig. 8 shows the identical nature of the cuts.

The cartridge cases found at the scene of the crime were branded FN, SFM, and AEP, and the cartridges seized with the accused persons were of the same three brands.

From this examination it could be stated:

(1) That the ammunition used in the crime and the ammunition seized with the accused persons was of the same manufacture and calibre.

(2) The tips of the bullets had been treated in exactly the same manner to convert them into expanding bullets. The instruments used for this purpose were of the same nature.

(3) The marks on the cartridge cases and bullets proved conclusively that both the Sûreté pistol and the Colt pistol had been used in the crime, and that it was the latter which actually caused the death of the Sirdar.

The presentation of this report put an invaluable weapon in the hands of the police, for they knew then with absolute certainty that they had caught the right men and had sufficient evidence to convict them. As a result confessions were obtained from both Enayats which incriminated several other people, and eventually eight persons were definitely implicated in the crime (excluding the driver of the taxi in which they escaped).

The houses of these persons were searched, and in that of Mahmoud Rachid (an engineer) a number of tools were found, including a quantity of saws, files, and two vices, which were examined, with the following result.

The vices had pieces of zinc fitted to the jaws to prevent the teeth of the jaws marking an object held in them. In these pieces of zinc a longitudinal depression was observed which had been made by clamping a body of a size similar to a 0.32 cartridge. In this groove traces of copper were found. It must be clearly understood that, although this depression and the copper fragments could readily be caused by clamping a cartridge, it could as readily be caused by clamping any other cylindrical brass or copper object. On taking the vice to pieces a certain amount of dust was found in the joints, and in this dust numerous bright metallic particles were observed. This dust was examined for nickel, cupro-nickel, and lead, for if a bullet were clamped in the vice for the purpose of cutting the tip one would expect traces of nickel and brass in the dust as well as possible traces of lead. The analysis proved the presence of traces of copper, zinc, and nickel in the dust. The combination of these metals is an extremely suspicious circumstance, but it must be kept in mind that ordinary brass may contain

traces of nickel, and that a mechanic may quite well have traces of all of these metals amongst his tools.

Saws.—None of the saws contained traces of copper, nickel, or lead on the teeth.

Files.—There were fifty-three files in the box, varying in fineness from rasps to key files. Brass was detected on several of these files.

It will be observed that all the tools required for cutting the bullets were present in the box. The tools were of the same nature as those actually used for cutting the bullets. The dust contaminating the tools was the same as the dust that would be produced by cutting the bullets. There was therefore a strong presumption that the tools were used for this purpose, but the available information was not sufficient to enable one to state conclusively that they were so used.

In the meantime Shafik Mansour (a lawyer, and one of the accused) stated that they had been in the habit of concealing the weapons in a secret receptacle made by unscrewing the bottom panel of a door in the house of Mahmoud Rachid. A further search of Rachid's house was made, and a door was found in which the lower panel was seen to have been tampered with. This was forwarded for examination.

It was found that the panel had been originally fixed in position by two nails on one side and four nails on the bottom. In addition to the nails, glue had been used to fix the panel permanently. The panel had been removed and the nails on the side replaced by screws. The bottom nails had been left.

On examination of the wood around the cavity in the door under the panel it was seen that the nail holes in the bottom were ragged and irregular and around them there was a series of smaller and larger punctures and scratches. These marks were caused by numerous attempts to replace the panel in position after removal. In carrying this out it was necessary to force the nails in the lower edge of the panel into the nail holes, and as it was difficult to get all the nails in at the first attempt various scratches and punctures were made in the wood. About thirty of these punctures could be counted around one nail hole. Many of these were distinctly old, in others it was impossible to give any opinion as to the time when they were made (Fig. 9). There were a number of hammer marks on the panel which were probably produced by knocking the panel tight. The condition of the nail holes indicated that the panel had been removed and replaced a considerable number of times. The inside of the receptacle in the door showed a number of indentations in the wood, and it could be shown that certain of these indentations exactly corresponded with marks produced by the fore-sight and back-sight of the Colt pistol. If the pistol was placed in position in the cavity both sights exactly corresponded in position with the marks in the wood. These impressions were found in different parts of the receptacle, and indicated that the weapon which caused them had been placed in the receptacle in four different positions. Twelve sets of these marks were to be seen. There were many other marks caused by hard substances being forced against the wood, and several of these corresponded with the sights of the Mauser pistol. There were many others, however, which could not be attributed to any of the pistols seized, and the presence of certain impressions of a milled surface strongly suggested that other metal objects, possibly other weapons, had been concealed in this receptacle. The dimensions of the cavity were 33.5 by 12.5 cm. and this space (shown in Fig. 9) accommodated the four seized pistols comfortably.

From the above examination it could be stated that the panel of the door had been removed and replaced a considerable number of times, extending over a long period; that the receptacle under the panel had been used for holding certain articles which caused scratches and indentations in the wood; that certain of these indentations corresponded exactly with the sights of the Colt pistol seized in the case, and that others corresponded with the sights of the Mauser pistol, suggesting that these two weapons had been secreted in the receptacle.

At the subsequent trial the eight accused persons were found guilty and condemned to death: seven of them were actually executed and the eighth had his sentence reduced to penal servitude for life.

SPECIFIC ANTITOXIN IN THE TREATMENT OF SCARLET FEVER.*

BY

A. GARDNER ROBB, M.B., D.P.H.,

VISITING PHYSICIAN IN CHARGE OF THE BELFAST FEVER HOSPITALS.

I wish to record some of the results which I have had, during the past few months, in the treatment of cases of scarlatina with specific streptococcus antitoxin, and shall confine my remarks to the results in cases treated within the first few days of the disease; not because good effects are only to be looked for in cases treated thus early, but because the results in cases receiving the serum within two or three days of the onset have been so striking as to leave with me no doubt of the very great value of the treatment. In such early cases the attack has been completely aborted, and desquamation and complications prevented, or greatly diminished; so much so that the quarantine time could be reduced by some 50 per cent.

In cases not coming under treatment until the fourth day of the disease or later the results are much more difficult to estimate, and it will require a much longer time—many months—before definite conclusions can be formed regarding the beneficial effects on the general course of the disease, and the power of the serum, when first given comparatively late, to prevent secondary complications and sequelae or to reduce their severity. I shall hope to report more fully at a later date.

Since 1885 it has been known that haemolytic streptococci were to be found in the throats of patients suffering from scarlatina in the early stage. In 1895 Marmorek prepared an antitoxic serum in the horse by injecting cultures of this streptococcus. This antitoxin was used in the treatment of cases, but the results appear to have been indefinite. In 1902 Moser similarly prepared an antitoxin from the use of which he believed he obtained beneficial results, but other observers employing this serum failed to confirm this. In 1905 Jockmann published a review of the work done along these lines, and examined the claims made that the haemolytic streptococcus so frequently found in the throats of scarlatina patients was the causative agent of the disease. He came to the conclusion that a good case had not been made out, and that this streptococcus was not the causative agent but a secondary invader. Work on the subject then lapsed and no important advance appears to have been made for some twelve years.

In 1917 Schultz and Charlton, experimenting with serum from convalescent cases of scarlatina, found that this serum, when injected into the skin of acute cases of the disease, while the rash was well marked, caused complete blanching of the rash in a small area at the seat of injection. They also found that the serum from some healthy individuals produced this result, whereas the serum from cases in the early stage of scarlatina did not possess this power. This was a great step in advance, but was not so recognized at that time. In 1923 Mair,¹ repeating these experiments of Schultz and Charlton, explained this reaction thus:

"Scarlet fever is apparently a general toxæmia and the rash only a manifestation of the toxin uniting with the tissue cells causing a capillary dilatation with swollen papillae. The serum injected neutralizes the toxin in the tissues and causes the disappearance of the rash. The negative reaction of the sera of acute cases of scarlet fever is simply due to the fact that antitoxin has not yet developed."

In 1919 Dochez, Avery, and Lancefield devised a new method for the differentiation of biologic types of haemolytic streptococci. This led to a further study of the haemolytic streptococcus so constantly found in the throats of scarlatina patients. Reports by Dochez and Bliss, Tunnichliff, M. H. Gordon, and Stevens and Dochez led to the conclusion that this haemolytic streptococcus was a specific type.

¹ Drs. George and Gladys Dick succeeded in producing experimental scarlatina in a volunteer by swabbing the throat with a pure culture of a haemolytic streptococcus from a case of scarlatina (1923). It was now established

beyond all reasonable doubt that this haemolytic streptococcus was the specific causative agent of scarlet fever.

The Dicks also demonstrated, in 1924, that Berkefeld filtrates of media in which the specific streptococcus is grown contain a toxin, and that this toxin, in suitable dilution, injected intradermally, produces a positive skin reaction (the Dick test) similar to the Schick test with the diphtheria toxin.

Dochez of New York described, in January, 1924, an antitoxic serum which he had produced in the horse by adopting a most ingenious method. In order to protect the streptococci from the phagocytic action of the leucocytes of the horse he injected liquefied agar subcutaneously into the horse's neck, and, when the agar had cooled and solidified, living *Streptococci scarlatinae* were injected into the agar. Thus protected the organisms survived and produced toxin which was taken up by the blood stream. After a course of immunization of six months the horse was bled and the serum tested in cases of scarlatina.

Employing this antitoxic serum, Blake, Trask, and Lynch obtained very good results in the treatment of cases of scarlatina, a single intramuscular injection of the serum in early cases being followed by prompt disappearance of the rash and symptoms of toxæmia and a very rapid convalescence without complications. They found also that the serum, injected intradermally in cases with early scarlatina rash, caused complete blanching of the rash at the seat of injection (Schultz-Charlton reaction). They also demonstrated that the toxin circulating in the blood of acute cases of scarlatina is completely neutralized within a few hours after the injection of Dochez's serum. They showed this by bleeding the patient immediately before treatment and obtaining positive Dick skin reactions in susceptible individuals, and by again bleeding at frequent short intervals after the injection of Dochez's serum. Even in some very toxic cases the Dick tests were negative as early as four hours after the administration of the serum.

In April, 1924, the Dicks reported the production of an antitoxin in the horse by a different method. They employed for immunization increasing doses of Berkefeld filtrates of media in which the specific streptococcus had been grown. This antitoxin also gave good results. Quite recently Messrs. Parke, Davis and Co. have put on the market an antiscarlatinal serum prepared by immunizing horses with injections of both the living organisms and of toxin. It is claimed that this serum is both antitoxic and bactericidal.

Ferry, Pryer, and Fisher report results in thirty cases of scarlatina treated with antitoxic and antibacterial serum in Detroit. In twenty-two of these the fever and symptoms promptly subsided and recovery was rapid. In five response was somewhat more tardy, but the results were good. In three cases the course of the disease did not appear to be influenced by the serum. Unfortunately the duration of the illness at the time the serum was first administered is not given in any account of this series which I have seen. This, in our experience, is an all-important point.

Last June Dr. Dochez was kind enough to send me a supply of his serum for trial in cases of scarlatina here. It was whole serum and the dose recommended was 30 to 40 c.cm. by intramuscular injection. Later he had sent on to me further supplies of serum prepared, by his method, by Messrs. Eli Lilly and Co., of Indianapolis. This serum was concentrated (by methods similar to those generally employed in preparing diphtheria antitoxin), the dose being reduced at first to 20 c.cm., and in the later supplies to about 10 c.cm. I have also, during the last few weeks, obtained supplies from Messrs. Parke, Davis and Co.; this product also is a concentrated serum.

Belfast has during the past few years experienced extensive outbreaks of scarlatina of fairly severe type. While the case mortality has not been very excessive (in 1,700 cases in Purdysburn Fever Hospital last year it was 3.3 per cent.), the incidence of complications—arthritis, severe adenitis, rhinitis, otitis, etc.—has been high, and the duration of detention in quarantine has been long. Although there have been many mild cases which could be released from isolation after four or five weeks, the average duration of

* A paper read before the Ulster Medical Society on December 3rd, 1925.

illness at the time of discharge from hospital was last year over six weeks. The "return-case" rate (taking a period of forty-two days) was 2.7 per cent. The case mortality in 800 cases in the first six months of this year was 2.1 per cent.

Such was the type of scarlatina in which we were able to test the results of this new treatment. The first supply of serum which I received from Dr. Dochez consisted of twelve bottles of 40 to 45 c.cm. each. I concluded that the best use to make of this for test purposes was to give it to cases of more than average severity who were admitted early in the attack. It was therefore given mainly to patients with intense rash who were not more than three days ill. (Some of it was given to advanced cases of very severe septic type; but that is another story.)

This serum was whole serum (unconcentrated) and the dose recommended by Dr. Dochez was 30 to 40 c.cm., according to severity. It was given intramuscularly. We started with this dose, but the results in the first few cases were so good that we attempted to conserve our very limited supply and to spread it over a larger number. In some cases in young children one bottle was divided between two, and in other instances two bottles were divided among three cases.

Fourteen early cases were thus treated with an average dose of 32 c.cm. The results were good, exceedingly good. In all fourteen cases there was a very rapid disappearance of the rash and of all toxic symptoms. Six were treated on the second day of illness, seven on the third day, and one early on the fourth day. Of the six treated on the second day three showed no desquamation, and three had fine powdery desquamation, only to be found by careful search. One had slightly enlarged cervical glands—they were just palpable—in the third week. There were no other complications. Of the seven cases treated on the third day, two had no desquamation, five had slight desquamation; three had mild cervical adenitis, two had slight joint pains—in one case confined to the shoulders for one day only, the other had pains in several joints for some five days; this patient had a history of having had rheumatic fever two years previously. The one case treated on the fourth day had mild desquamation, but no complications. In all these cases the fever subsided very rapidly. It has been customary in the reports of cases treated with this serum in America to lay stress on the critical fall of temperature; personally, I do not attach very much importance to rapid fall of temperature, as in my experience such changes in the temperature charts are common when any form of serum is used. In thirteen of the cases in this series the temperature had reached normal, and remained there, by the fifth day from the onset; in the remaining case it did not finally come down till the sixth day. As a rule the temperature was down to normal, and stayed there, in twelve to forty-eight hours after the administration of the serum. Three of these fourteen cases developed urticarial serum rashes, but in none did this give rise to any serious discomfort. No attempt was made to discharge these cases from hospital before the ordinary time, as we were anxious to watch them far into convalescence.

I was very greatly impressed by these results and eager to make further tests, but it was several weeks before I was able to secure further supplies. As they came to hand they were used in the same way, and we are now able to obtain the serum in quantity. The results continue good.

Up to the present we have treated 140 cases by this method. Many of the later cases have been discharged from hospital after periods of isolation very much shorter than had ever been possible before. In the last few weeks we have released from isolation over twenty cases whose quarantine time, from the onset of illness, varied from seventeen to twenty-four days. The cases thus early released had, of course, come under treatment very early in the attack.

I shall mention a few cases which may be taken as typical of the series.

CASE I.

A man, aged 29, was admitted on the second day of illness. He had a vivid general rash, very acute throat affection, and the temperature was 103°. He was given 10 c.cm. of concentrated serum. The temperature fell to normal the following day, and so

remained. The rash had completely disappeared in thirty-six hours. The throat symptoms rapidly subsided, but the fauces remained bright red for several days. There was very slight powdery desquamation, confined to the shoulders, on the ninth day, none elsewhere at any time. There were no complications, and he was discharged on the twenty-third day from the onset.

CASE II.

A boy, aged 13, was admitted on the second day with intense rash and very acute throat affection; he was very toxic and delirious, with a temperature of 103.4°. He was then given 10 c.cm., and this dose was repeated some twenty hours later. The symptoms subsided rapidly; the temperature fell to normal on the fifth day, and he had no further fever and no complications. There was slight desquamation on the abdomen only. Convalescence was rapid, and he was discharged on the twenty-first day from the onset.

CASE III.

A child, aged 3, was admitted within twenty-four hours of the first noting of illness. He had then well marked general erythema, and vivid rash with very acute throat affection, and the angular glands were already enlarged. He was given 10 c.cm.; forty-eight hours later there was no trace of rash and only slight redness of the fauces. There was no desquamation at any time and no complications. On the ninth day he had an urticarial serum rash, which was visible for two days. Thereafter he remained well, and he was discharged on the nineteenth day.

We have had several such cases in young children, the type in which it is so common to have throat, nose, and ear complications, necessitating long detention in hospital.

CASE IV.

A junior medical student, aged 18, was admitted on the second day of illness. On the first day he felt slight sore throat on rising in the morning, but attended his classes that day. In the evening he had very sore throat, and severe headache. The following morning he had acute inflammation of the throat and nausea, and the rash was noticed late in the afternoon. He came into hospital that night. Forty-three hours from the first indication of sore throat he was given 10 c.cm. of serum intravenously. He had then very intense deep-coloured erythema, with well marked general rash, very inflamed throat, was moderately toxic, with a temperature of 103°. Two hours after the serum was administered the temperature had risen to 103.6°; but it then fell steadily, and was normal in thirty hours. The erythema had gone, and the rash was much faded twenty-four hours after the serum was injected. Traces of rash and slight pigmentation could be seen for another two days. There was considerable redness of the fauces for five days. He was then feeling quite well. There was no desquamation, no complication, and no serum rash. He remained well, was discharged on the seventeenth day from the onset, and returned to his classes in the university on the eighteenth day. He had passed through a sharp attack of scarlatina and only missed thirteen days' classes. This was the only case in which we have given the serum by the intravenous route; in all others it has been injected intramuscularly.

These results are exceptionally good, but they are typical of those we have had when it has been possible to administer the serum well within the first forty-eight hours of illness. Every hour appears to count, and when the case has advanced into the fourth day or later the effect on the rash and throat symptoms is much more gradual, desquamation is more marked and general, and cervical adenitis, though always mild, has been observed in many cases.

The following may be taken as typical of cases first treated later than the third day.

CASE V.

A girl, aged 6, was given serum on the fourth day of illness; she then showed very intense rash and very acute throat. The temperature fell to normal by the sixth day, but the throat remained very inflamed and angry for a week, desquamation was general and fairly free. There were no complications.

CASE VI.

This patient, a girl aged 11, was sister to Case V, and was admitted at the same time; the attack in her case was of about equal severity, except that the rash was rather more marked; the throat signs were of equal severity, but the duration was one day, or rather more, shorter at the time the serum was injected. In this case the rash disappeared very much more rapidly, the throat cleared up in a couple of days, and there was no sign of desquamation and no complications.

Of the 140 cases who have received this treatment some are quite recent, but 100 are available for review. In this series the incidence of complications has been exceedingly low. Scarlatinal rheumatism has been almost entirely absent, with the one exception already mentioned in a patient who had a history of rheumatic fever two years previously.

There has not been a single case of severe cervical adenitis, and only a small percentage have had angular

glands large enough to be easily palpable. We have not once seen a purulent discharge from the nostrils, but two cases, which both first received the serum on the third day of illness, did develop otorrhoea of mild type. There has not been a case of late nephritis.

I wish again to emphasize that this report deals only with cases which have come under treatment early in the disease.

As the result of the experience I have had with this treatment, I am very hopeful that we have now a remedy which gives promise of great usefulness, and if the estimate we have formed is found to be the general experience we may look for a reduced case mortality, a great reduction in the very severe complications and after-effects of scarlatina, and also, with the cutting down of the necessary quarantine time, we may hope for much relief to the strain which scarlet fever so often puts on the accommodation of isolation hospitals, and for a material reduction in the cost of such institutions. As a prophylactic this new method should prove of great service.

In the preparation of this serum there are at present great difficulties. The fact that the ordinary laboratory animals cannot be made use of to measure the antitoxic value of the serum is a great handicap. The need of the moment is a reliable and simple method of estimating the potency of any particular batch of serum. At present this can only be done in human beings, either by the effect on the intradermal reactions with toxin in healthy susceptible individuals or by the Schultz-Charlton reaction in early cases with scarlatina rash. Even by these methods it must be acknowledged that the estimate which can be formed is very crude. No doubt time will solve the difficulty, but until it is solved there is, I fear, danger that serum of low potency may find its way on to the market. We know that this has occurred with other antitoxic serums.

It would appear that the two essentials in securing maximum results with this method are—serum of high standard, and very early cases.

SALIVARY CALCULUS.

BY

G. H. EDINGTON, D.Sc., C.M., F.R.F.P.S.G.,
 SURGEON, WESTERN INFIRMARY, GLASGOW.

THE occurrence of calculi in the salivary apparatus is well known, although infrequent as compared with the incidence of stone in the biliary and urinary systems. This comparative infrequency, hardly to be termed "rarity," is such that the presence of salivary calculi may be overlooked and the condition escape recognition when the patient is first seen.

In almost all textbooks of surgery mention, more or less detailed, is made of salivary calculi, and it is now possible to formulate a fairly typical syndrome. It happens, however, that patients sometimes do not spontaneously furnish a typical history, and the latter may or may not be elicited by interrogation. In such cases as the last the discovery of calculi is dependent on the surgeon being alive to the possibility of their presence, and keeping in his mind the salient clinical features of the condition.

Clinical Course.

The patient usually complains of pain in the floor of the mouth, associated with a swelling there which appears or increases during mealtimes, at which times the pain also is aggravated. Such a history is almost more than suggestive of obstruction in Wharton's duct, the common situation of a salivary calculus. Should, however, the calculus be in Steno's duct, pain will be experienced in the cheek and swelling may be observed there.

When the stone has existed for some time, and has reached a size sufficient to produce obstruction of the duct, enlargement of the salivary gland concerned may be expected. In the case of the submaxillary there may be a visible swelling below the jaw. Swelling of the gland indicates more or less

inflammation of that organ, and on palpation it is found to be of firm consistence. As with the duct, pain may be experienced in the swollen gland during mealtimes, and helps to differentiate the firm swelling from that of malignant disease of upper cervical lymphatic glands. Further help in the differentiation is obtained by bimanual palpation, which shows the external to be continuous with an intrabuccal swelling in the posterior part of the floor of the mouth.

The patient sometimes complains also of a disagreeable taste in the mouth, in which case a streak of pus will usually be seen exuding from the duct orifice, or further back in the floor of the mouth. The occurrence may or may not be associated with an acute inflammatory exacerbation. If marked inflammation exists the presence of calculus may be very successfully masked.

Inspection of the floor of the mouth in a suspected case may show swelling and redness of the orifice of Wharton's duct, and if a probe introduced into the duct strikes the stone the diagnosis is made certain. Sometimes one end of a lenticular-shaped calculus may protrude from the orifice, the inflamed or ulcerated margin of which grasps the stone. In the absence of such findings, palpation of the floor of the mouth may demonstrate a hard body in the course of the duct. In some cases mobility of the concretion within the dilated duct is a characteristic feature. In another type of case the calculus may be palpated far back and apparently lodged in the substance of the gland.

Spontaneous extrusion of the calculus may occur; more often removal has to be undertaken. This is accomplished by slitting the orifice of the duct, or incising directly over the concretion. In the latter case the duct is steadied by fixation forceps applied immediately posterior to the concretion. When the incision is made pus not infrequently wells out, carrying the stone with it. The calculus may not immediately escape through the incision, in which case I have found Lister's ear-hook of assistance. If the calculus be mobile it sometimes retreats into a loculus, may for long defy the surgeon's efforts, and be dislodged only with great difficulty. In cases where the above measures fail, and in cases where the stone is situated in the gland or in the commencement of the duct and cannot be extracted in the floor of the mouth, extirpation of the submaxillary gland from without is called for. While a comparatively easy operation as a rule, extirpation is sometimes rendered very difficult by inflammatory matting of the parts, and not only may the buccal cavity be opened into, but the lingual nerve may not escape injury.

Physical and Chemical Characters of Calculi.

Of yellowish-white colour, and sometimes of faintly greenish hue, salivary calculi may be spherical, torpedo-shaped, or cylindrical. Their surface may be smooth, but is often finely tuberculated. While usually the calculus is solitary, examples of multiple concretions are occasionally met with. Their composition is made up by mineral salts and animal matter. The salts concerned are variously given by different authors. According to Erichsen,¹ Waterhouse,² Ivor Back,³ and H. Bailey,⁴ they are principally calcium phosphate and carbonate; Butlin and Spencer⁵ say chiefly calcium phosphate with some carbonate; Syme⁶ mentions calcium phosphate alone, and Pearce Gould⁷ calcium phosphate and some ammonio-magnesium phosphate. Analysis was made in four of my cases (vide infra), and showed either phosphates alone or along with mere traces of carbonate.

Such salts as are found in the calculi occur also in the saliva, the composition of which is as follows: calcium phosphate and carbonate, sodium carbonate, potassium sulphate, and chlorides of sodium and potassium; carbonates are particularly abundant; mucin is abundant in submaxillary and sublingual, and absent in parotid, saliva (Howell,⁸ with whom Flack and Hill⁹ in the main agree).

Etiology.

The calculi are the result of the precipitation of the salts of the saliva. The exciting cause of the precipitation is not definitely known. Butlin and Spencer (loc. cit.) think that calculus formation is apparently connected with the presence of a plug of inspissated mucus. The same view is elaborated

by Back (loc. cit.), who considers that the genesis of the calculi is intimately connected with inflammation of the duct of the gland concerned, a plug of mucus containing bacteria being formed, and salts deposited thereon; such inflammation depends on septic conditions of the mouth. Be that as it may, the surgeon meets with many septic mouths without calculus formation; and, on the other hand, it is often found in cases of calculus that the mouth does not show any special foulness. It seems to me that Back's view may be taken as a working hypothesis, while the cause of the precipitation is not definitely known.

Situation.

It is not known whether precipitation occurs primarily in the duct or in the gland substance. Clinically, however, the concretions are usually found in the duct of the gland concerned, although in the case of the submaxillary gland it is not rare to meet with them apparently in the parenchyma. Their relative frequency in Wharton's duct may depend on the accessibility of that structure to palpation.

All writers are agreed that calculus is much more frequently found in the submaxillary duct than in those of the other salivary glands. Andrews¹ gives the frequency as about five times greater than in any other gland. Bailey gives the ratio as a little more than 50 to 1; in my cases it is 8 to 1. This probably depends on the relative abundance of mucin in submaxillary saliva (Howell, supra). Bailey (loc. cit.) quotes Christopherson's² observation that in the Sudan parotid are much commoner than submaxillary calculi.

CASES.

The following nine cases, seen during the past twenty-five years, illustrate and are grouped according to the signs and symptoms furnished by individual patients. The submaxillary was implicated eight times, the parotid once.

A. SUBMAXILLARY.

(1) "Mealtime" Syndrome.

CASE I.¹—Female, aged 30, seen 1906. Submaxillary swelling, right, for six weeks; three weeks later dental extraction without improvement; swelling painful at mealtimes; disagreeable taste in mouth; gland stony hard, and pressure on it caused pus and mucus to exude from duct orifice. Attempted probing failed; no calculus felt on palpating duct; incision in floor of mouth failed to identify duct. Gland excised through external incision, and found to contain calculus, size of small pea, in dilated commencement of duct.

CASE II.—Male, aged 24, seen September, 1922. Discomfort in right submaxillary region, for nine years, especially during meals; twelve months ago had abscess below tongue. Prominent mucosa at orifice of Wharton's duct, and in line of duct. Palpation revealed hard body in duct; mucosa fixed by forceps, and incised, evacuating stone measuring 7 by 10 mm., with smooth hard coat; distal end bluntly tapered, proximal end thicker and bare; subsequent probing negative.

CASE III.—Male, aged 29, seen May, 1925. Pain and swelling in left side floor of mouth, and in neck, worse at mealtimes; swallowing hindered. Stony hard swelling in left submaxillary gland; sublingual thickening, juicy, in floor of mouth; no calculus felt; subglossitis. Calculus passed spontaneously, and discomfort passed away. Calculus spherical, measured 7 by 5 by 4 mm. Analysis (Dr. Cappell) showed composition to be almost entirely of calcium phosphate, with traces of carbonates and organic matter; no sulphate present, and only a trace of magnesium and iron.

CASE IV.^{1,2}—Male, aged 16, seen November, 1900. Swelling "under tongue" for ten days. Redness and swelling of orifice of right Wharton's duct; in centre of reddened area, small yellowish-white point, calcareous when struck by probe; felt very hard between finger and thumb. Mucosa proximal to swelling fixed by forceps, and incision freed stone, which was then squeezed out by forceps, and followed by stringy mucus; no distension of duct, or swelling of gland. Concretion flattened ovoid, 6 by 4 by 3 mm.; nucleus visible through cracks in rind. Analysis (Dr. W. B. Brodie) showed composition to be entirely calcium phosphate, with some albuminoid matter (mucus); carbonates, chlorides, and sulphates absent.

(2) Swelling in Floor of Mouth.

CASE V.^{1,2}—Male, aged 38, seen June, 1925. Swelling under tongue and in right submaxillary region, for one week. Swelling and signs of inflammation in line of right Wharton's duct; probe struck drical calculus. Incision evacuated pus in which escaped a small cylindrical calculus measuring 9 by 4 mm. Analysis (Dr. Cappell) gave precisely similar results as in Case iii. An element of confusion in

this case when first seen by his medical attendant was the presence of an enlarged gland of two years' duration at angle of left mandible. This gland was clearly tuberculous. There was a history of enlarged glands in childhood, and scarring was present in the left anterior triangle, and over the sterno-mastoid.

(4) Submaxillary Swelling, Acutely Inflamed.

CASE VI.—Male, aged 55, seen May, 1924. Submaxillary swelling, left side, of some years' standing; rapid enlargement of one week's duration, with pain on swallowing and on protruding tongue, and carache on same side. Firmness of swelling suggested malignancy, but no lesion could be seen or felt in tongue or fauces. No evidence of calculus. Increase of swelling and onset of oedema in floor of mouth posteriorly led to external incision, evacuating flakes of pus. During convalescence the mouth became very foul. Three weeks after incision pus observed far back in floor of mouth. Pus came from opening in inflamed area far back in floor, without induration of cancer. Later (February, 1925) swelling in floor of mouth subsided with discharge of pus, and reaccumulated. Pus came from opening in inflamed area far back in floor, without induration of cancer. Later (February, 1925) palpation detected stony hardness anteriorly to fauces; bimanual palpation showed continuity with enlarged submaxillary gland externally, the whole mass moving freely on mandible. Extirpation of submaxillary gland was carried out with difficulty, owing to nerve damaged during removal. Healing took place after slow con- valescence, and with slight "anchoring" of tongue to floor of mouth and anaesthesia. Examination of gland after removal showed embedded in intrabuccal part a large ovoid calculus, 14 by 20 mm., with tuberculated surface. Similarly tuberculated cal- careous material was present on wall of containing cavity. His- tological examination of gland (made by Dr. Cappell) showed involu- tion and atrophy of secreting tissue, chronic inflammatory changes and much fibrous tissue.

(5) Concretion Presenting at Orifice of Duct.

CASE VII.—Male, aged 31, seen September, 1922, with tip of salivary calculus projecting from orifice of left Wharton's duct. Inflammation of fold in floor of mouth, and enlargement of sub- maxillary gland. Portion of concretion, measuring 12 by 7 mm., extracted; remainder felt by probe in duct, and extracted the following day by Lister's car-hook. It measured 10 by 7 mm., was cylindrical in form, and with cup-like extremity towards duct orifice. Probed duct subsequently to 1½ in., with negative result.

(6) History of Concretions being passed from Duct.

CASE VIII.—Male, aged 22, seen December, 1916. Had history of "enlarged gland at left angle of mandible, opening into mouth by a sinus, sometimes emitting a concretion." There had been long- continued discharge from left Wharton's duct, and periodic swelling of submaxillary gland; no calculus palpable. Submaxillary and portions of sublingual gland excised; firmly adherent to tissues of neck.

B. PAROTID.

CASE IX.—Male, aged 20, seen November, 1916. For three years had had swelling of left cheek, varying in size. On palpation, calculus felt at commencement of Steno's duct (posteriorly). Removed through horizontal incision in skin of cheek over stone; not ascertained if in duct or gland tissue. No ulceration or inflammation at orifice of duct. No sutures; wound healed on ninth day. Swelling of gland persisted, especially in anterior part below level of duct. Duct probed with negative result. Analysis (Captain W. Campbell, R.A.M.C.) showed inner core of cretaceous matter, outer coating of inspissated mucus. Ovoid shape, measured 7.5 by 6.5 mm. Composition: calcium, magnesium, and phosphorus pentoxide.

REMARKS.

The above series is far too small for statistical purposes. It illustrates, however, the comparatively high incidence of calculus in the submaxillary apparatus; the high propor- tion of males; the absence of constant clinical picture; the obscurity of diagnosis by inflammation (Case vi); and in the four specimens analysed the part taken by phosphates. It is interesting to note, also, that Cases ii and vii were brothers, and that the solitary parotid case (ix) occurred in a soldier in Egypt, although the trouble had probably started before he went there.

CARCINOMA OF THE STOMACH AFTER GASTRO-JEJUNOSTOMY.

BY

SIR GEORGE T. BEATSON, K.C.B., K.B.E.,

M.D. EDIN.,

CONSULTING SURGEON, GLASGOW WESTERN INFIRMARY; SENIOR SURGEON,
GLASGOW ROYAL CANCER HOSPITAL.

A good deal of discussion has recently taken place as to the liability of a simple gastric ulcer to become carcinomatous, and there is considerable difference of opinion as to the frequency of such an occurrence. The appearance of carcinoma in the case of a long-standing gastric ulcer would be in keeping with the now widely accepted fact that it is a frequent sequel of irritation in any form, and would be a development that might quite well be regarded as both possible and probable. In the same way, considering the frequency with which gastric lesions are now treated by gastro-enterostomy, followed as this operation must be by the presence of a certain amount of scar tissue (also a favourable nidus for the cancer process), it would not be surprising if such an artificial opening might, in the course of years, become the seat of carcinoma. Relative to these two points the following case, which was under my care at the Glasgow Royal Cancer Hospital, is of interest, and, I think, has some bearing.

A car-conductor, aged 52, married, was admitted on November 21st, 1921, suffering from a tumour of the stomach. The letter sent with the patient gave the information that he had been operated upon by Sir Kennedy Dalziel at the Western Infirmary, Glasgow, in 1910, when gastro-enterostomy was performed. It further stated that in 1920 he was readmitted there with a recurrence of gastric disturbance, and laparotomy was performed, when it was found that there was a carcinomatous growth of the lesser curvature, stretching down the posterior wall and involving the new opening of the gastro-enterostomy. There were also secondary growths in the peritoneum beneath the left ribs. Under these conditions nothing further was done, and the wound was closed.

When admitted to the Glasgow Royal Cancer Hospital he was in a very anæmic and emaciated condition, weighing only 6 st. 11 lb., his height being 5 ft. 2 in. The gastric tumour could be felt on palpation. The clinical history of the case while in the Cancer Hospital was somewhat uneventful, but he had periodic attacks of gastric disturbance, with some vomiting and, at times, diarrhoea. The matter vomited was chiefly the food that he had taken. He got gradually weaker, and died on April 8th, 1922.

Post-mortem Examination.

The report of the *post-mortem* examination stated that: "The body was that of an extremely emaciated man. There was a central abdominal scar from an old operation. The left leg was very oedematous, and the right was also swollen, though to a lesser degree. *Thorax:* The lungs were oedematous and congested. *Heart:* The myocardium showed brown atrophy. There was atheroma of the coronary arteries and of the aorta. *Abdomen:* A firm mass was present, occupying the pyloric part of the stomach. This organ was opened along the greater curvature. An extensive malignant ulcer with raised, thickened, and rounded edges, was found at the pylorus, stopping short at the pyloric sphincter. This ulcer was about four inches in diameter, with irregular eroded base. The middle finger could be passed through the sphincter into the duodenum. A posterior gastro-enterostomy had been performed. Its stoma was represented by a conical ulcerated depression, one and a quarter inches in diameter and about the same depth. The edges were thickened and continuous with the ulcer margins. The stoma presented the same appearance as the ulcer, and was evidently malignant. A probe could not be passed into the distal part of the attached jejunum, but the proximal side admitted the forefinger. The liver was fatty, slightly enlarged, and showed numerous nodules throughout. There was thickening and shortening of the omentum near the pylorus. The mesenteric glands were enlarged. There was nothing of note in the kidneys, and the spleen was small and soft. A thrombus was present in both iliac veins, but not extending into the inferior vena cava. The microscopic section showed a typical adenocarcinoma of the stomach, with invasion of the mesenteric lymph glands and secondary nodules in the liver. The edges of the gastro-enterostomy opening were also found to be malignant and of the gastric type.

From the report of the *post-mortem* examination it is evident that the malignant disease was of gastric origin, and the condition of the gastro-enterostomy wound—namely, that a probe could not be passed into the distal part of the jejunum while the proximal side admitted the forefinger—indicated that the food must have passed more or less in a vicious circle through the duodenum and back into the stomach.

It is unfortunate that there is no record in the Western

Infirmary journals to show the reason for the operation of gastro-enterostomy done twelve years previous to the patient's death, nor is there any note made of the presence of any ulcer. An interview with the patient's daughter gave the following information: At the beginning of his illness her father complained of diarrhoea, which continued for a long time, and in consequence of which he was sent to the Western Infirmary, where, as noted, an operation was performed, she states, for dilated stomach. Decided improvement in his health followed the operation, and the diarrhoea ceased, so that he was able to go back to work after having been off duty for a year subsequent to the operation. He seems to have been able to continue his work for eight or nine years, when he began to become emaciated. He was again sent to the Western Infirmary, where the abdomen was opened a second time, and the condition already described was found. Her mother was told that at the seat of trouble there was a tumour almost up against the new passage, and that practically nothing further could be done. Shortly before his admission to the Glasgow Royal Cancer Hospital some vomiting showed itself, but there was no history of hæmorrhage at any time. The paleness present on his admission to the hospital was a matter of recent date, as previously he had a fresh colour. He was a heavy smoker, but temperate as regards alcohol.

In view of the above statement of the patient's daughter it would be a fair inference that the gastro-enterostomy was done for a dilated stomach, probably connected with some ulceration in the vicinity of the pylorus and leading to some obstruction at that orifice, necessitating the gastro-enterostomy operation. If this be the case, in view of what was found at the *post-mortem* examination two surmises are possible: one is to assume, as I have done, the existence of an ulcer which in time became malignant and extended into the gastro-enterostomy wound; the other, that the malignant action commenced in the wall of the gastro-enterostomy wound on the gastric side, and, by extension, involved the old ulcer. The balance of weight of opinion is probably in favour of the former extension, but it does not put out of court entirely the possibility of the latter.

In the *Lancet* of June 13th, 1925, Mr. Sherren is quoted as having stated that he had never seen carcinoma develop after gastro-jejunostomy. I learn from Mr. Sherren, however, that I had not correctly interpreted his statement, and that he did not say that he had never seen carcinoma develop after gastro-jejunostomy, but that he had never seen the late development of carcinoma after gastro-jejunostomy had been carried out for a small mobile ulcer on the lesser curvature. How far the above case has a bearing on the latter point one cannot say with certainty, but I think that the case has some value in connexion with the question of ulceration of the stomach being a forerunner of carcinoma, and I must leave other surgeons to draw their own conclusions as to its being an instance of a gastro-enterostomy opening becoming the seat of cancer.

THE POSITION OF THE STOMACH IN HEALTHY BRITISH AND AMERICAN SUBJECTS.

BY

ROBERT ORTON MOODY, M.D.,

ASSOCIATE PROFESSOR OF ANATOMY IN THE UNIVERSITY OF CALIFORNIA;
HONORARY DEMONSTRATOR IN RADIOLOGY AT UNIVERSITY
COLLEGE, LONDON.

A STUDY of the position of the abdominal viscera is being carried on at the x-ray laboratory of the department of anatomy at University College, London, for the purpose of determining the normal positions and their range of variation in healthy living subjects. Radiographs have been taken of 53 men and 20 women. This is too small a number from which to draw definite conclusions; but the results warrant the interesting, though at present tentative, suggestion that in the British the stomach occupies a lower position than it does in Americans.

With the subjects in the standing position, after a meal of two ounces of barium sulphate in two cups of malted milk, the lowest part of the greater curvature of the stomach was found below the interiliac plane, a line drawn

between the highest points of the iliac crests, in 80 per cent. of the men and in 95 per cent. of the women.

At the University of California a similar study of 1,000 healthy young adults—an equal number of men and women—showed that the lowest part of the greater curvature of the stomach was found below the interiliac plane in only 75 per cent. of the men and in 88 per cent. of the women examined in London.

In the English, more often than in the American, the lowest part of the greater curvature of the stomach is found more than two inches below the interiliac line. It is found as low as this in 31 per cent. of the English men and in 57 per cent. of the English women, and in only 43 per cent. of the American women.

The position of the lowest part of the greater curvature of the practically empty stomach has also been recorded. With only one swallow of the barium mixture in the stomach this is found to be below the interiliac line in 50 per cent. of the men and 85 per cent. of the women.

This preliminary report is presented in the hope that it will interest many to volunteer to have their radiographs taken at University College and thus help to determine the truth of the tentative conclusion that in the English the normal position of the viscera is not quite identical with that of Americans. The discussion of the significance of this difference is deferred until a larger series is available as a basis for comparison.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

OCCLUSION OF THE RECEPTACULUM CHYLI: PROGRESSIVE EMACIATION: DEATH.

NOTICES occur from time to time of cases where progressive emaciation in adolescents or young adults ultimately results in death, and at the *post-mortem* examination no cause of death is discoverable. Such a case has recently been reported where a girl aged 16 years began wasting away, and when she died three years later weighed only 3 st. 13 lb.

This case recalls one which occurred in the wards of the late Professor Greenfield at Edinburgh in the early eighties of the last century. A young man was emaciating rapidly and no cause whatever could be found. In a clinical lecture Professor Greenfield remarked that the only thing he could think of to explain such a case was tuberculous obstruction of the receptaculum chyli of the thoracic duct. The *post-mortem* findings were reported to be negative, as no cause of death could be found. I could not be present till the *post-mortem* examination was concluded, but received permission to dissect out the receptaculum chyli, and found its lumen completely occluded by inflammatory tissue apparently of a tuberculous nature. The thoracic duct was not occluded.

Professor Greenfield's diagnosis of emaciation due to interference with the passage of the lymph stream from the intestines to the superior vena cava was therefore justified, and the girl above alluded to may have been a similar case, as it is not likely that an ordinary examination would have included a dissection of the receptaculum chyli.

Consulting Physician, Birmingham General Hospital.

CONGENITAL PACHYDERMATOCELE.

The following case is, I think, worthy of being recorded by reason of its rarity.

A female infant, aged 3 weeks, was admitted to hospital with a congenital overgrowth on the left side of the head and face. The father and mother are healthy. There had been no untoward incident in the pregnancy, but labour was very difficult and instrumental. The child weighed at birth 8½ lb., was rather large, and did not take food well. On admission it was in a low state and there was a large mass hanging down from the place where the left ear should have been. As the illustration shows, the mass was convoluted and fissured, and a serous discharge was exuding from

it; this discharge had a peculiar and disagreeable odour. Extending from both sides of the tumour to half-way over the left cheek in front, to the occipital protuberance behind, to the parietal eminence above, and the angle of the jaw below, was a patch of raised convoluted tissue, the surface of which was irregular and thrown into folds. These folds somewhat overlapped each other and extended, more or less, from side to side. They increased in depth and width from above downwards. In the middle of the pendent mass there was a fissure, 1 inch deep and 2½ inches wide. Outside this patch, and extending to the middle of the nose and half-way down the neck, was a peculiar creasing of the skin, slightly elevated above the normal level, which was practically dry. The nose was of the *retroussé* type and slightly deformed. Another abnormality was the presence of a tooth in the middle of the upper jaw simulating an incisor. When, some weeks later, I excised a small piece of tissue, the mass bled profusely. The pathologist's report on the specimen was as follows: "The section shows an extensive and irregular basal-celled hyperplasia of the epithelium, apparently related to the spaces of an angiomatous portion of the tissue. There is no clear evidence that this is yet a malignant new growth, and it bears more resemblance to a naevus. There is considerable difficulty in interpreting isolated fragments, and if the whole tumour (?) should be excised we recommend that an entire portion should be sectioned. No history is given, but the section is suggestive of Darier's disease."

Mr. D. Greig, conservator of the museum of the Royal College of Surgeons of Edinburgh, on seeing a photograph, suggested that the case might be one of pachydermatocele. The pathologist now appears to agree with Mr. Greig, as he writes:

"The suggestion of Darier's disease was made merely upon the histological appearance of the portions of skin which you sent us. It is quite evident from the photograph that the case was one of that peculiar form of cystic hygroma which has received the name of pachydermia or pachydermatocele. Treves's 'elephant man' was an example of the condition. The proliferated epithelium is not particularly abnormal, though it becomes so secondarily; it is growing in such profusion because of its exaggerated vascular supply. Darier's disease is an instance of the same phenomenon, but the cause of the increased vascularity is usually a small naevus, while only large naevoid growths are called cystic hygromata."

Thus the condition seems to be a congenital pachydermatocele. As the child died soon afterwards no further investigations were possible.

I am indebted to Dr. Horan for permission to publish this case.

Leeds. M. SOUTASKY, M.D., F.R.C.S. Ed.

HYPODERMIC INJECTION OF LUMINAL-SODIUM IN STATUS EPILEPTICUS.

LUMINAL has been successfully employed on a large scale in the treatment of epilepsy, but, so far as I know, there are no records of the employment of the soluble sodium salt by hypodermic injection in status epilepticus, although Dercum records a case of chorea insaniens so treated with favourable results. My experience is limited, but the results have impressed me so favourably that I feel impelled to publish them, in the hope that others may take advantage of what I believe to be a simple and efficacious line of treatment.

Case 1.—Female, aged 42. After three fits in half an hour with incomplete recovery between each, 1½ grain of luminal-sodium was given. After this the fits became less frequent, and the patient was discharged the next morning an improved woman. Luminal-sodium was given; the fits gradually ceased within seventy-five minutes.

Case 2.—Male, aged 39. Half a grain of luminal-sodium was given by hypodermic injection after status epilepticus had existed for about thirty minutes. This dose was repeated after about four hours as there was only slight improvement. The fits ceased soon after the second injection. This patient from time to time has a series of fits in rapid succession without passing into true status epilepticus; 1½ grain of luminal-sodium subcutaneously will abort these attacks.

Case 3.—Male, aged 21. The patient had forty fits in one hour and was in status epilepticus. A subcutaneous injection of 3 grains of luminal-sodium was followed by immediate cessation of the fits. On another occasion this man had twenty-four fits during the day; he was given 1 grain of luminal-sodium subcutaneously, and had no fits afterwards.

I know of no ill effects from this treatment, even after a dose of 3 grains. Luminal itself is insoluble. Luminal-

sodium is readily soluble in water, but the solution employed should be freshly prepared, as it deteriorates and becomes worthless after keeping a few days.

W. J. T. KIMMER, M.R.C.S., L.R.C.P., D.P.M.,
Deputy Medical Superintendent, Hill End Mental
Hospital, St. Albans.

A VAGINAL CALCULUS.

In April, 1925, an Arakanese multipara, aged 44, was admitted to the Akyab Hospital complaining of having had pain in the back and discharge for the last five months. It was found that the vagina was so contracted by dense fibrous tissue that it would not admit one finger. Several dense fibrous bands ran across the vagina from the anterior to the posterior wall. With a director a stone was felt lying in the posterior fornix; this was removed by forceps after stretching the fibrous bands running across the vagina. A small vesico-vaginal fistula was found which

admitted a small probe. The stone measured 1.8 cm. in length and 1.2 cm. in breadth.

The report of the Royal College of Physicians Laboratory, Edinburgh, on the stone was as follows: "The stone consists chiefly of calcium phosphate with very faint traces of uric acid. When the stone was broken up a small nucleus resembling a fruit seed was found in the centre."

It appears to me that this stone must have been actually formed in the vagina, and from the dense fibrous tissue around it it must have been there for many years without apparently causing any inconvenience.

W. F. BRAYNE, M.B., Ch.B.,
Lieutenant-Colonel, Indian Medical Service.

PITUITARY EXTRACT TO CORRECT CONSTIPATION DUE TO MORPHINE.

A MAN suffering from advanced pulmonary tuberculosis with severe laryngeal involvement was admitted to this institution on July 4th as an emergency case. He was considered to be in *extremis* at that time. His main symptom has been agonizing superior laryngeal pain, radiating up to both ears. He has had to have morphine in doses increasingly large and frequent to alleviate this distressing symptom.

For the last two weeks he has been having four to five hourly doses of morphine, 1/2 grain, subcutaneously (making an average of 2½ grains of morphine daily). Many laxatives and purgatives, with or without nux vomica and strychnine, were used in turn, but for two weeks the gut wall had been practically paralysed, and the resulting distension and abdominal pain began to trouble him almost as much as the laryngeal pain. I tried an injection of 1 c.cm. of pituitary extract, and he had a thorough and copious evacuation within ten minutes; the injection has been repeated every afternoon since, and the effect has been as rapid on each occasion.

A boy under treatment for diabetes insipidus has for some months been having 1 c.cm. of pituitary extract every day; this reduced the urinary output from 26 to 2 pints in the twenty-four hours. On questioning him, he said that he always had a "cold feeling in his stomach" a few minutes after the injection, and a bowel action within half an hour. This suggests that the action on peristalsis is uniform and unaccompanied by any undesirable after-effects. As the organism does not acquire a tolerance to endocrine extracts, the dose does not need to be increased.

E. OBERMER,
Medical Officer.

NEPHRITIS FOLLOWING TONSILLITIS.

DURING the last six months I have had what I think may have been a rather remarkable series of cases of acute nephritis. There have been eight cases, and all live within a radius of about fifty yards. In all the attack was preceded by acute tonsillitis. The patients have been of both sexes, and of ages varying from 5 to 25 years. The onset of the symptoms of acute nephritis has been from twelve to fourteen days after the attack of tonsil-

litis had completely cleared up. There appeared to be nothing unusual about the tonsillitis except that the attacks were rather severe for four or five days. Swabs were negative to diphtheria. The patients were up, apparently recovered, and in about their usual health when the symptoms of acute nephritis came on quite suddenly—headache, pain in the back, pallor, oedema of the face, hands, feet, and legs, scanty urine loaded with albumin and blood, and in some cases vomiting. All recovered completely in about three weeks, with complete rest in bed, strict milk diet, large quantities of thin barley water, and free purging by magnesium sulphate. Is it possible that there was any relationship between the tonsillitis and the nephritis? How is the occurrence of all these cases within a small area, which is not congested, in this small country town to be accounted for?

CLINICAL AND SCIENTIFIC PROCEEDINGS.

MONMOUTHSHIRE DIVISION.

A WELL attended meeting of the Monmouthshire Division was held at the County Hall, Newport, Mon., on December 15th, 1925, when Dr. ROCYN JONES presided.

Mr. DUNCAN C. L. FITZWILLIAMS, of St. Mary's Hospital, London, gave an address on cancer and the latest methods of treatment. By way of introduction he gave a summary of the views about cancer in times past, and added that the ideas held to-day might very probably have been abandoned two generations hence. The recent research work on cancer was fully considered and its possibilities discussed; a hopeful "wait and see" attitude was advised. The causes of the increase of cancer were touched upon, and the futility of many of the theories which ascribed the disease to diet or civilization was exposed. Considerable attention was paid to pre-cancerous states, and the recent advances in laboratory work in connexion with them. Epithelial cells might be cancerous, although they had not as yet invaded the tissues; this had been proved by transplanting these cells into mice. The single character of cancer growths was insisted upon, due possibly to the growth inhibiting cancer development elsewhere. The conclusion drawn was that cancer in its early stages must be a local disease, and, if local, must be capable of cure in a large percentage of cases if early diagnosis was made and removal effected. The increase in the severity of the operations had not brought a corresponding improvement in the results, and the better results now obtained were due rather to earlier diagnosis than to the thoroughness of the operations. Cancer for statistical purposes could be divided into accessible and inaccessible forms. Accessible cancer of the breast, tongue, and rectum should be diagnosed in an early state, and if treated adequately before there were signs of malignancy should yield a cure in 80 to 90 per cent. of cases. Such figures had actually been obtained in early cases, both in the breast and in the tongue, where otherwise the ordinary mortality figures were as bad as anywhere in the body. The difficulties of early diagnosis were pointed out, and its necessity insisted upon. "Cancer weeks" as held in America were mentioned as an advance in this direction. It should be understood that early diagnosis and local operations were to be depended on, rather than late diagnosis and huge or so-called radical operations, in all of which the results must be considered very poor. Other methods of treatment were mentioned, such as x rays; their limitations and great uses were also considered. Injections of colloidal forms of metal were touched upon, and in conclusion Mr. Fitzwilliams begged his audience to impress upon the laity the fact that cancer was a curable disease, and to try to combat the fixed idea at present held that this was a disease from which it was hopeless to seek relief.

At the close of an appreciative discussion the CHAIRMAN moved that the heartiest thanks of the Division be given to Mr. Duncan Fitzwilliams for his excellent address, which set out from the preventive medicine standpoint the most practical methods he had yet encountered. The address had

been so provocative that a promise had been obtained from Mr. Fitzwilliams that he would later submit a scheme of collecting the histories and records of treatment for the executive to consider, in order that the co-operation of the county council of Monmouthshire and the borough council of Newport might be enlisted with reference to dealing with the cancer problem in their area.

Dr. A. W. HAYLES, in seconding the resolution, said that from his standpoint as a general practitioner he welcomed the suggestions thrown out by Mr. Fitzwilliams, and would do all in his power to help in devising a cancer scheme for Monmouthshire.

Reports of Societies.

MEDICINAL INDUCTION OF LABOUR.

At a meeting of the North of England Obstetrical and Gynaecological Society at Sheffield on November 20th, 1925, Mr. M. H. PHILLIPS in the chair, Dr. K. VERNON BAILEY (Manchester) read a paper on the clinical aspect of medicinal induction of labour.

Dr. Bailey said that since the publication of A. C. Williamson's paper on the induction of labour by the use of castor oil and quinine, which appeared in *Surgery, Gynecology and Obstetrics* in 1922, much interest had been taken by the staff of St. Mary's Hospitals (Manchester) in this particular treatment, and during the last few years labour had been induced very often by this method, or a slight modification of it. The efficiency of a combination of quinine and castor oil in stimulating the uterus to contract, and the specific action of those drugs on the uterine muscle, which had been discussed by Williamson, had been definitely established. The drugs were administered in the following way. A dose of 2 ounces of castor oil was first given, followed one hour later by half an ounce of a mixture containing quinine sulphate gr. x, acid. sulphur. dil. mx, glycerin mxx, sp. chlorof. mv, and water to the half-ounce. One hour after this a simple enema was administered, and two hours later another dose of the mixture. Three hours later a further dose of the mixture was given, and another in four hours. Some patients in this series were also treated with pituitrin in 1/2 c.cm. doses half-hourly, commencing five hours after the last dose of quinine, and 3 c.cm. in all given. The method resembled that described by Watson; 40 gr. of quinine were used, but the treatment was discontinued where nausea or ringing in ears was complained of. The chief indication for induction of labour by medicinal means was uncertainty as to the progress of the labour, and cases in which induction by mechanical means was contraindicated, owing to the possibility of Caesarean section being required. The risk of sepsis after Caesarean section was increased by previous vaginal examination; this applied to induction by mechanical means where delivery by Caesarean section eventually became necessary.

Many cases in which there was doubt as to the progress of labour terminated successfully, the child being born normally and without forceps, after labour had been induced medicinally. During the course of such a labour Caesarean section could be resorted to if necessary without increased risk. In his series of cases the primiparae exhibited some degree of minor pelvic contraction. The presentation and position being normal, the foetal head might be (1) mobile at the pelvic brim, possibly due to causes other than the pelvic contraction; (2) fixed at the pelvic brim, but exhibiting some very slight degree of "overlapping"; (3) fixed but high, its greatest diameter being above the plane of the pelvic brim. The pregnancies ranged from eight months to post-maturity, and it was considered that delivery *per vias naturales* was a sound possibility; thirty-eight cases were of this type. Multiparae usually presented a history of previous difficult labours due to pelvic contraction, or of progressively large children; forty-nine cases were of this type.

Cases of uterine inertia might continue unduly; if there was dilatation of the os uteri, or if the membranes had ruptured some hours previously, it might be better to

recommence active labour as soon as possible, considering both the child and the risk of sepsis to the mother. Another type of case admirably suited to this treatment comprised certain cases of accidental haemorrhage and marginal or lateral placenta praevia. Many of these patients when first seen were in a condition of temporary relief following a smart haemorrhage, or exhibited a constant but slight loss, the uterus was contracting irregularly and at long intervals, or not at all, and there was little or no dilatation of the os. Medicinal induction of labour in these cases, where the risk of sepsis was greatly increased by interference, was attended by great success. The harmlessness of the treatment, and the high percentage of successful results obtained, had led to the employment of it in other types of case where induction might justifiably be undertaken by mechanical means, and in cases where medicinal treatment had not been successful alone in starting labour, induction by bougies, within twenty-four hours afterwards, usually succeeded. Post-maturity reacted well to this treatment (twenty-five cases), and the method was used for severe albuminuria or threatened eclampsia in eight cases. Though labour might not commence after this treatment alone, Dr. Bailey believed that the specific action of quinine on the uterine muscle was maintained to such a degree during the following twenty-four hours that added mechanical stimulation (by bougies) quickly brought about regular contractions. Patients differed so much physically and temperamentally that it was difficult to define the effect of this treatment on the progress of labour. Shortening of the first stage appeared to result sometimes, but the most regular feature was the relatively painless nature of the uterine contractions which occurred in 70 per cent. to a greater or less degree. In some patients it was so marked as to approach a condition of painless uterine contractions, and only careful observation of the uterus showed that labour was in progress. The pulse and temperature in an uncomplicated case showed no variation from that in normal labour. Considering the type of case the number of forceps deliveries was comparatively small (nine of the seventy-eight), and in these the low forceps operation was employed for the usual indications. Dr. Bailey believed that the course of quinine given as described, even if it failed to initiate uterine contractions, increased the tone of the uterine muscle itself. If pituitrin was given when the uterine muscle was in this condition, immediately after the course of quinine, it was not so liable to produce that state of irregular and spasmodic contraction which was known to cause rupture of the lower uterine segment. Pituitrin was given to the first nineteen patients of his series without any untoward occurrence. The percentage of successes (68.4) with its use was not so high, however, as that obtained by the use of quinine and castor oil alone (72.7 per cent.). He believed it was unsound to employ a drug like pituitrin, of admittedly great power but of uncertain action, in the first stage of labour. The later fifty-five cases of the series were conducted without its use. Dr. Bailey thought, however, that pituitrin might be of assistance, with negligible risk, in induction of inevitable abortion when the uterus did not exceed the size of a five months pregnancy. It was especially useful in the completion of an inevitable abortion at anything up to three and a half months. From this up to five months a course of quinine and pituitrin, followed by a hydrostatic bag, was very successful. He believed that the danger of producing irregular and spasmodic uterine contractions by the administration of pituitrin was minimized by the quinine course immediately preceding it, and that its use in the production of complete abortion at the dangerous stage up to three and a half months, or even up to five months, was legitimate. Conditions were not then favourable to uterine rupture during labour. Beyond this stage, he believed, pituitrin should never be used, as the production of anything but regular and uniform uterine contractions was extremely dangerous. In this series labour had been successfully induced by purely medicinal means in 57 of the 78 cases (73 per cent.). In a small number of the earlier cases pituitrin was used in addition to quinine and castor oil, which were used alone in the majority of the cases. The percentage of successes was greater in those

where pituitrin was not used; it would appear, therefore, that the addition of pituitrin in no way increased the possibility of success. The high percentage of successful inductions by medicinal means assigned to this method has a place in obstetrics. The proportion of successes was higher than Williamson's (46.6 per cent.) and Muschalli's (58.6 per cent.), but not so high as Watson claimed with the additional use of pituitrin (90 per cent.). Williamson, in reviewing his cases, had stated that the noteworthy points about the successful ones were: (1) the patient was due, or overdue, in point of time; (2) the head was fixed or beginning to engage; (3) the cervix was partially or completely obliterated and the external os would admit a finger. In the series here reported there were many successes with premature cases and in others, where the foetal head was mobile and the cervix closed. From a survey of these it appeared, therefore, that quinine was definitely able to act upon a closed cervix, a point which Williamson apparently considered doubtful.

In conclusion, Dr. Bailey expressed the view that there was a definite class of case in which this treatment was particularly useful—cases in which induction of labour was indicated but where methods involving vaginal intervention were contraindicated (border-line cases between the normal and abnormal from the purely mechanical point of view). Only in two cases of the series was it found necessary to perform Caesarean section after labour had been induced by this means. Had it been necessary to perform Caesarean section after mechanical attempts to induce labour had been made, the prognosis would have been graver than after the use of this medicinal method.

Mr. M. H. PHILLIPS (Sheffield) expressed his strong approval of this method of induction, especially when the cervix was infected. He would not care, however, to rely on it in cases of placenta praevia. He wished to know the relative proportion of successes in premature and full-term or post-mature inductions. The time element also was important.

Dr. DOUGAL (Manchester) had used the quinine and castor-oil method during the last three years, and found it most useful. He had never seen any ill effects follow either in the mother or child, but he had recently heard of a case where the child was born asphyxiated and did not recover, and this misfortune was thought to be due to the powerful uterine contractions induced by quinine. He would like to know whether Dr. Bailey had met with any similar cases in his series. Like most other methods, it was particularly successful when the pregnancy was about, or past, full term, or when the ovum was dead, but these were often the cases where a simple and harmless method was most called for. He had had cases of missed abortion where the uterus had completely emptied itself after the administration of these drugs. Cases of delayed onset of labour were often a source of considerable anxiety to those in attendance, and for these he strongly recommended the castor-oil and quinine method. He had known such patients start labour very quickly, and deliver themselves within twenty-four hours. Occasionally the method was almost too successful, and he related a case where labour started about three hours after the commencement of the method, and was completed within an hour and a half before either the accoucheur or his anaesthetist could arrive. He had not much experience of pituitary extract in induction of labour, but thought that there could be no objection to its use before the commencement of uterine contractions. He certainly would not hesitate to use it, if necessary, in those cases where it was desired to empty the uterus during the first half of pregnancy.

Mr. W. W. KING (Sheffield) had used the quinine and castor-oil induction a large number of times in the last few years, but he usually gave colossal calcium as a preliminary; he believed that this added to its usefulness.

Mr. J. CHRISTOLAR (Sheffield) said he was much interested in the analgesic effect which Dr. Bailey had described as following the use of this method. He did not think it was right to employ this method in the treatment of placenta praevia.

Dr. BAILEY, in reply, said that medicinal induction was only used for true accidental haemorrhage or the high type of marginal placenta praevia; it would not be employed in cases of central placenta praevia. Sufficient data were not

to hand to make any definite conclusion possible with regard to the lapse of time between the commencement of the treatment and delivery; in some cases delivery occurred before the termination of the treatment, and in others up to twenty-eight hours after its administration. In cases of contracted pelvis the pelvis was carefully examined and efforts made to approximate the foetal head to the pelvic brim in cases subjected to this treatment. Dr. Bailey had never seen a case in which the child had become asphyxiated on account of the force of the uterine contractions. Of the seventy-eight cases of the series, all but thirteen were not in labour at the commencement of the treatment. In no case had calcium been employed, as suggested by Mr. King.

ESTIMATION OF THE PATENCY OF THE FALLOPIAN TUBES.

At a meeting at the Liverpool Medical Institution on December 17th, 1925, a joint contribution on sterility due to impalpable tubal defects, by Drs. BLAIR BELL, R. E. ROBERTS, J. ST. G. WILSON, and S. B. HERD, was read by Dr. HERD.

Dr. Herd outlined the accepted methods of treatment for female sterility, and showed that vaginal operations were frequently useless. The adoption of the tubal patency test by insufflation was very valuable as a means of controlling surgical procedures and avoiding unnecessary operations. Reference was made to the work and methods of Rubin, Dickinson, Forsdike, and Blair Bell, and a description given of the technique and apparatus employed by the last named, a hand bulb, reservoir manometer, and cannula being used, and air employed. Thirty-one patients had been tested in this way without serious discomfort or disability. Radiological examination was always used, and, in all cases in which operations followed, the previous diagnosis of the state of the tubes was confirmed. Insufflation was only used for diagnosis, and no therapeutic value was claimed for it.

Dr. R. E. ROBERTS gave an account, with illustrative skiagrams, of the radiological features in the diagnosis of patency of the Fallopian tubes. The uterus having been insufflated, any air which had passed through the Fallopian tubes would tend to rise to the highest point in the peritoneal cavity, this point depending on the position of the patient. After the uterine insufflation the patient sat up or stood, and after a short interval in which the air had opportunity to rise in the peritoneal cavity, an x-ray examination was made of the diaphragmatic and hepatic area in the erect position, a skiagram being invariably taken. If the Fallopian tubes were both occluded, no air would have entered the peritoneal cavity and the upper border of the liver could not be distinguished from the diaphragm. If, however, one or other Fallopian tube was patent and air had entered the peritoneal cavity by this route, the air would have risen to the under surface of the diaphragm and would be shown in the skiagram as a translucent area between the diaphragm (which appeared as a delicate curved line) and the liver, the extent of this translucent area depending on the amount of air which had passed in. Even very small quantities of air could as a rule be demonstrated by this method, but it was conceivable that if the tubes were almost occluded the amount of air entering the peritoneal cavity would be so small that it might become entangled in the mesenteric folds and so fail to reach the subdiaphragmatic area.

Mr. ST. G. WILSON thought that inflation was most suitable for cases of "one-child sterility" when several years had followed the last confinement. Inflation alone could not always be relied on for a correct result, and he therefore advised injections with lipiodol in all cases which gave negative results with inflation. The clinical signs of passage of air through the tubes was unsatisfactory; he therefore always recommended the use of radiology.

Prognosis of Auricular Fibrillation.

Dr. WALLACE JONES contributed a note on some points in the prognosis of auricular fibrillation, based on the analysis of statistics of a series of patients attending the

heart department at the Royal Infirmary. The dominant factor in prognosis was the condition of the heart muscle. Information with regard to this would be naturally classified as clinical evidence and electro-cardiographic findings. The symptoms accompanying the onset were very important and, when marked, indicated limitation of the reserve force of the heart, and in consequence considerable myocardial damage. The investigation was made to determine the expectation of life from the time when the cases first presented themselves with symptoms of cardiac failure until they died. It was shown that auricular fibrillation in these cases was more serious in senile than in rheumatic heart disease; that in mitral stenosis the expectation was slightly lengthened by the presence of auricular fibrillation, while in aortic regurgitation this effect was more marked. The prognosis was better in females than males in all types. In the electro-cardiographic findings the presence of a bizarre Q.R.S. curve was of serious significance.

PLASTIC SURGERY.

At a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, held on December 4th, 1925, the President, Mr. R. C. B. MAUNSELL, in the chair, Mr. T. P. KILNER delivered an address on the principles of plastic surgery and gave a lantern slide demonstration of case records illustrating the following procedures.

Mr. Kilner at the outset gave a description of the method of cutting and applying Thiersch skin grafts and their employment for the obliteration of a buccal sulcus, for freeing the lip and improving its contour in secondary hare-lip operations, for replacing the lost mucosa of the syphilitic nose, for the treatment of ectropion of the eyelids, for reconstruction of the eye socket, and for burns of the hand. In dealing with Wolfe skin grafts, he described the replacement of forehead skin removed in making forehead flaps for rhinoplasty and the replacement of burnt skin of nose. He mentioned the following forms of simple flap: forehead to eyelid region; forehead to chin region based on the superficial temporal artery; forehead to cheek; a full thickness, muscle-bearing flap; the angle of mouth; and simple advancement flaps on abdominal wall in treatment of x-ray burn. He gave an account of the use of fat grafts for a suppressed scar of the cheek and eyelid and of several cases of partial and complete reconstruction of the nose. Dealing with syphilis of the nose, he described the closure of a perforation involving the eyelids and the treatment of typical syphilitic deformity by intranasal skin graft and later a cartilage graft. He detailed the method of preparing the Gillies tubed-pedicle flap, and reported several cases illustrating its wide field of usefulness. These included burns of the hand; extensive reconstruction of the upper lip and cheek; complete reconstruction of the chin and lower lip (including bone graft to mandible); very extensive burn contracture of the neck; repair of partial loss of the external ear (including cartilage grafts); very extensive traumatic loss of skin of thigh and knee region, followed by contracture and complete failure to heal; various other limb conditions—ulcers, wounds, etc.

The President said he was specially interested in Mr. Kilner's remarks about the colour of grafts afterwards, as he himself had constructed a few artificial noses, and had found it very hard to get the graft a good colour. He asked why in two cases of mole, one in the region of the eye and the other in the region of the chin, Mr. Kilner had chosen forehead flaps instead of flaps from the neck.

Mr. M. T. BOURKE referred to the valuable advice he had received from Mr. Kilner in treating a case of very bad facial deformity in which the patient had greatly improved.

Mr. W. PEARSON said that he had had some experience of skin grafting during the war, usually on portions of the body more easily treated than the mouth cavities described by Mr. Kilner. He personally had had 95 per cent. of completely successful cases; his operations usually concerned granulating surfaces, and he thought it was

easier to get grafts on granulating surfaces than on raw surfaces. He let the surface granulate for about ten days before putting on the grafts. He used a perfectly dry technique, without any liquid on the knife.

Mr. H. MEYER, referring to Wolfe grafts, said that Mr. Kilner had mentioned that he only cut the graft the exact size of the area he was going to replace; would he do this in areas which were likely to extend? In a recent case encountered the skin loss was on the back of the hand, and any attempt to flex the fingers tended to enlarge the raw area. Regarding skin grafts for burns, he thought the important thing in preventing contraction was to graft early. In Thiersch grafting he did not use silver foil, and left the wound completely exposed to the air.

Mr. W. DOOLIN said that plastic surgery had been practised by the Indians and the Italians, who had recognized the need of a pedicle flap; the Indians took the flap from the head and the Italians from the forearm. When replacing a keloid scar, was it likely that another keloid would form and another operation be necessary? If so, this would nullify an operation which was done purely for the cosmetic result.

Mr. KILNER, replying, said that there was no skin which matched the face skin as well as forehead skin; abdominal skin was not of the same texture, and never looked so well. In rhinoplasty cases it was comparatively easy to excise scar tissue from the inside of the nose in the later stages. He thought that cases of grafting on limbs were much more difficult than intraoral cases. He would always prefer to graft on a newly made surgical surface than on a granulating surface. He never made a Wolfe graft bigger than the area to be replaced, but he always ensured that the area was at its largest before grafting. The grafting of cases of burns early, before contraction occurred, was very important. The productive factor in keloids was tension. He often treated keloid scars by radium therapy, both before and after operation.

OSTEITIS DEFORMANS.

At a meeting of the Electro-Therapeutics Section of the Royal Society of Medicine on December 18th, 1925 (Dr. A. MACGREGOR in the chair), Dr. R. E. ROBERTS and Dr. J. MORRIS CORRY read a paper on osteitis deformans (Paget's disease of bone). A brief account of the history of the disease, its incidence, etiology, and pathology, was given, and a general survey of the symptomatology and radiological examination of sixteen patients was added. The earliest symptom was, as a rule, pain in the lower limbs, especially after walking; in some of the cases muscular weakness was complained of. Deformities and limb enlargement were as a rule late changes, and spontaneous fracture had occurred in three cases. In several of the cases Paget's disease was unsuspected till a radiological examination of the affected part had revealed the characteristic bone changes, the diagnosis being confirmed by a further x-ray examination of the skull, pelvis, and other bones. Often widespread bone changes were discovered in parts where there had been no clinical evidence of disease. The importance of making a radiological examination of any adult case of obscure limb pain was thus made clear. A detailed account of the x-ray appearances at various stages of the disease was given, with illustrative skiagrams, and deductions made as to the pathological processes producing them. Attention was drawn to the similarity of x-ray changes found in osteitis deformans and osteitis fibrosa, suggesting that both conditions were closely allied if not identical. Treatment of the disease was at present unsatisfactory, but in one of the cases definite radiological evidence of improvement was found to follow the use of parathyroid extract, cod-liver oil, and calcium lactate, the x-ray appearances of the skull and femur suggesting that the disease was becoming, or had become, quiescent. The paper was discussed by Mr. THURSTAN HOLLAND and Drs. SHILLINGTON, SCALES, COLDWELL, JORDAN, PARKES WEBER, and COLLINGSWOOD.

Dr. P. J. BRIGGS read a paper on methods of examination of the pelvic caecum, in which were described and illustrated three methods for bringing a low caecum and appendix out of the pelvis for proper palpation.

Rebiefus.

ABDOMINAL AND PELVIC SURGERY.

CONTRIBUTIONS to surgical literature by Professor RUTHERFORD MORISON are always welcome, and his latest book deals, in the main, with acute, subacute, and chronic abdominal lesions.¹

In the introduction the progress of the art of surgery is traced in an illuminating way through the Listerian days to the present time. Although since his youth surgery has to a large extent passed gradually from the hands of the general practitioner into those of the specialist, Mr. Morison regards the general practitioner as the most important unit of the medical profession. He emphasizes his responsibility for early diagnosis, and urges him to move quicker in dealing with abdominal emergencies; he regards the results as still bad, and holds that "the chief cause of death is at the present and always has been—delay." As is well known, he is a warm advocate of team work, but disapproves of the division of special ailments into departments which are too watertight.

Prominence is given to the importance of diagnosis throughout the book, and everywhere the author's sound knowledge of physiology is evident. Individual diagnostic points of all the surgical abdominal diseases are illustrated by detailed accounts of clinical cases personally observed. In this connexion it may be noted that he records a fatal case, unique in his experience, where operation before the appendix had ruptured failed to save life.

Difficulties are emphasized by records of failure; he urges greater care in diagnosis, and deprecates the prevailing "open the abdomen and see" fashion. Numerous aphorisms might be picked out, but we will quote only a few typical examples (each illustrated by clinical evidence):

Abdominal injuries. "Beware of the diagnosis 'only winded' after an abdominal contusion or of the 'trivial wound' in an abdominal wall."

Urinary calculus. "A sudden bad pain extending from the kidney to the bladder and attended by a rigor suggests stone in the pelvis of the kidney and blocking its outlet." And "A similar pain, though more severe and extending down to the testicle or labium, suggests the passage of a stone into the ureter."

Pyosalpinx. "Capricious hæmorrhage associated with pain and recurrent attacks of pelvic peritonitis suggests pyosalpinx."

Intussusception. "A sudden attack of crying and vomiting in a healthy, generally male, child, suggests intussusception."

Apropos of the choice of an operating surgeon, Mr. Morison writes: "Many can play at golf after prolonged instruction and practice, but few can play golf. Unless the golf is in it can never come out. There are many operators, but few surgeons."

The section on the after-treatment of patients who have undergone operation is so well done that it could with advantage be printed separately and circulated among all house-surgeons and nurses.

The text and print are good, and the illustrations most helpful.

It is a difficult book to review, for it is unique, and in all parts, whether it be diagnosis or treatment, remarkably good. It has the charm of simplicity, and is full of sound practical wisdom set down in plain understandable language. Its two main merits, however, are that it embodies solely the author's views, the views of a keen observer of wide experience, and is free from all ambiguity.

A good teacher is dogmatic, but the dogma must be sound; the book is typical of Professor Morison, for his helpful dogmatic statements are useful to all. The book was professedly written for general practitioners, but it is equally valuable for consultants (including gynaecologists), and should be read by all surgical teachers. It is worthy of a handy place on every medical practitioner's bookshelf.

CARDIAC THERAPEUTICS.

THE book on cardiac drugs² by Dr. L. CHEINISSE gives an account of all the important remedies used for heart disease in France. The chief drugs described are the cardiac glucosides, including digitalis, strophanthus and squill, calcium chloride, camphor, and quinidine.

The book is of particular interest because it indicates considerable differences between cardiac therapy in France and in this country. The therapeutic action of the cardiac glucosides is discussed at some length, but little reference is made to the important work done in this country and in America which in the last twenty years has profoundly modified this branch of therapeutics. The article on quinidine is much more complete, and it is to be noted that Dr. Cheinisse claims that he was the first (in 1921) to bring to the notice of French clinicians the discoveries made by Wenckebach and Frey in 1918. When discussing the action of camphor he mentions the interesting fact that during the war the shortage of vegetable oils led to the use in France of vaseline as a solvent for camphor in hypodermic injections, and that such injections frequently were followed, after a long latent period of many months, by the appearance of local tumours which showed malignant characters. Vaseline injected subcutaneously is apparently a dangerous foreign body which may cause the appearance of large tumours that may grow and invade the deeper tissues.

Near the end of the book is a short chapter on cardiac opotherapy in which the effects of saline extracts of minced heart given by the rectum are discussed. Enthusiastic supporters of this line of treatment are quoted, but it is only just to say that Dr. Cheinisse does not himself support these claims.

ANCIENT HEALING GODS.

PROFESSOR JAYNE has made a laborious investigation of the literature of ancient civilizations with the object of putting together accounts of the healing deities. The result is a collection of great scientific value. His book, entitled *The Healing Gods of Ancient Civilizations*,³ is unusually well documented and systematically set forth, and he exhibits a scientific and critical judgement that is all too rare among students of medical history.

It is said that scepticism is the first duty of the man of science. This is no less true of the historian of science. It is extraordinary how many statements pass current in works on the history of medicine for which no ultimate evidence is forthcoming. From such faults Dr. Jayne's work is free. He ranges over the civilizations of Egypt, Assyria, Phœnicia, India, and Iran, as well as the Greek, Roman, and Celtic worlds. No man, it is true, can be a first-hand authority in all these fields, but, so far as we have been able to test, Dr. Jayne's cautious and critical spirit has prevented him from relying on any but first-hand investigators.

Despite these virtues, this excellent book appears to us to be based on a fundamental anthropological fallacy. This fallacy is often encountered in works on the history of medicine and in collections put together for the purpose of illustrating the history of medicine. It is the fallacy that assumes that before the rise of scientific medicine man was in the habit of distinguishing, or was indeed capable of distinguishing, disease as a separate entity. This does not seem to have been the case. The reading of the Bible alone should be sufficient to disprove it. Man suffered good and evil at the hands, as he supposed, of supernatural beings, and all supernatural beings were, in this sense, disease gods and gods of healing. To write a history of gods of healing would thus be to write a complete mythology. What Professor Jayne has done is to separate from the other gods, in a somewhat artificial manner, those with whom archaeologists and historians have so far succeeded in associating rites in connexion with disease. The list is always growing, and there is reason to

² *Les Médicaments Cardiaques.* Par Dr. L. Cheinisse. Paris: Masson et Cie. 1925. (51 x 81; pp. 178. 14 fr.)

³ *The Healing Gods of Ancient Civilizations.* By Walter Addison Jayne, M.D. Newhaven: Yale University Press; London: Humphrey Milford, Oxford University Press. 1925. (Roy. Bro. pp. xi + 569; 7 plates. 23s. net.)

believe that it will one day be identical with the list of the gods themselves. Professor Jayne himself calls attention to this in his preface, but he has not followed the matter to its logical conclusion.

In other respects Dr. Jayne has done a good and useful piece of work. Much of the book is of great interest to the ordinary reader. Its excellent arrangement, its admirable index, and its bibliography greatly facilitate reference. These qualities would alone be sufficient to gain and retain for it a special place in the literature of medical history.

SOME HOSPITAL REPORTS.

THE fifty-eighth volume of *St. Bartholomew's Hospital Reports*,¹ edited by a new committee, returns to its familiar binding and shape, after an experimental change into a crown octavo volume. In a short note on the history of the *Reports* the contents of the first volume in 1864 are recalled, and of the writers in the original volume two, Sir William Church and Sir Dyce Duckworth, survive full of honours unto this present. There are three sympathetic obituaries—on Dr. E. E. Klein, Dr. H. H. Tooth, and Dr. Herbert Williamson. Dr. Klein, who came from Austria to England in 1871 as assistant professor at the Brown Institute, was primarily a histologist, but entirely self-taught, became the only general bacteriologist in this country, and for years exerted a very great influence in the development of the subject in this country. There are eight articles on professional subjects, and lists are given of the officers of the hospital, of additions to the library and museum, and the proceedings of the Abernethian Society and of the Paget Club are reported. Writing on the vicissitudes of a patient with trigeminal neuralgia, Mr. L. Bathe Rawling states that he is not convinced that injections of alcohol, which must be intraneural or intraganglionic, make subsequent surgical procedure in the way of exposure of the ganglion, its root and branches, more difficult. He adds that were he a sufferer from this dread disease he would "most certainly fly to alcohol injection first, falling back on the surgeon when, and if, that method failed."

After a short essay by Dr. Hugh Thursfield on the treatment of meningococcal meningitis, there is a note on the detection of tubercle bacilli in the cerebro-spinal fluid by Dr. R. G. Canti, who demonstrated its presence in 17, or 85 per cent., of 20 cases of tuberculous meningitis; he found that the chances of success are much increased by previous incubation of the whole fluid. Dr. C. Langton Hewer's article on splanchnic analgesia is illustrated by three figures showing the technique of this method, which has the great virtue of diminishing shock from operative trauma. Mr. Wilfred Shaw deals with the relation between cyclical changes in the ovaries and similar events in the endometrium. The control of the intestinal flora is considered by Dr. L. P. Garrod, who concludes that a "normal intestinal flora" as such does not exist, and that the gravest doubts must be cast on the alleged pathogenicity of faecal streptococci.

The concluding number of the seventy-fifth volume of *Guy's Hospital Reports*² opens with an article by the Regius Professor of Medicine at Oxford, Sir Archibald Garrod, on Alexander John Gaspard Marcat (1770-1822), who was physician to Guy's Hospital (1804-1819), was with his friend, Dr. Yelloly, much concerned in the formation of the Medical and Chirurgical Society in 1805, and in 1817 wrote an essay on the chemical history and medical treatment of calculous disorders, which he dedicated to Wollaston. A further contribution to the study of the physical fitness of men assessed by various methods is made by Professor M. S. Pembrey, Mr. W. D. Hambley, and Mr. E. C. Warner, who conclude that there is not any single real test, other than the old one of trial and error, for physical fitness in every and any kind of occupation, and that physical fitness is relative and not identical with

good physique; they think that the pulse is for many reasons the best test. In the third instalment of the article on massage and remedial exercises in medicine Dr. G. H. Hunt considers diseases of the lungs and pleurae; he divides the subject into (1) local treatment—namely, emptying cavities and bronchiectases, and expansion of collapsed lung, and (2) general treatment to improve the circulatory and respiratory conditions and so the patient's general health. The successful editor, Dr. A. F. Hirst, contributes three papers: a short one on tuberculous infection of a chronic gastric ulcer; an interesting account of diverticula of the colon; and a discussion on the diagnosis of cancer of the stomach, an abstract of which served as the introduction to the discussion in the Surgical Section at the Bath meeting of the British Medical Association. This is supplemented by an analysis of fifty selected cases at Guy's Hospital by Dr. N. L. Lloyd. The results of splenectomy for acholuric jaundice, especially the changes in the fragility of the red blood corpuscles, are considered by Dr. J. M. H. Campbell and Mr. E. C. Warner, who detail four cases, three in one family, and conclude that while splenectomy removes the symptoms it does not increase the resistance of the red cells to haemolysis, much more than splenectomy normally does, and only very rarely, if at all, brings the fragility back to normal. The symptoms are therefore due to the haemolytic activity of the spleen and not to the fragility of the red cells, which is probably an underlying inherited condition in the familial cases. Dr. A. F. Knott, pathologist to the New Lodge Clinic, provides an article on the significance of coliform bacilli in the duodenum, based on the experience gained from 172 routine examinations of bile obtained from the gall bladder by the duodenal tube; he finds that pathogenic coliform bacilli occur in 90 per cent. of biliary lesions as compared with an incidence of 30 per cent. in other conditions. The treatment of acute rickets by the mercury vapour lamp is considered with moderation by Dr. J. F. Carter-Brain and Mr. A. A. Osman.

THE NATURE AND ORIGIN OF CANCER.

In connexion with the post-graduate classes arranged by the medical faculty of Vienna for the year 1924, it was proposed to include a series of lectures on carcinoma, which should furnish those attending the course, most of whom were medical men in actual practice, with a concise statement of the views at present held with regard to the nature and origin of the disease, its leading clinical features, and the main principles of its treatment. In order that medical men should be put in possession of something less evanescent than the subject-matter of a series of lectures is apt to prove, it was further proposed to embody the lectures in a book. The proposal has been carried out under the auspices of the Austrian society for the investigation and prevention of cancer, and twenty-eight of the leading members of that society delivered a series of thirty lectures, which have now been issued in a single volume.³

There can be no doubt of the utility of a book of this kind. Not so many years ago the conception of carcinoma may be said almost to have been embraced in the two words "medullary" and "scirrhous"; since that time our knowledge has been extended, not only by means of the scalpel and microscope, but also by chemical, bacteriological, radiological, serological, statistical, and other methods, and the disease has been produced experimentally in animals. The busy practitioner has no time to follow the intricacies of the subject, and is probably more bewildered than informed by any attempt to do so. He desires to know briefly what is the practical outcome of all this research, and in the volume referred to he will find concise statements on this head by recognized authorities in the subject. Another advantage in a book of this kind is the total absence of all preliminary matter—definitions, classifications, and so forth, requisites for enabling the student to pass his examinations; practical matters such as:

¹ *St. Bartholomew's Hospital Reports*. Vol. lviii. London: John Murray, 1925. (Demy 8vo, pp. xx + 113; 3 figures, 2 charts, 21s. net.)

² *Guy's Hospital Reports*. Vol. 75 (vol. 5, fourth series), No. 4, October, 1925. Edited by Arthur F. Hirst, M.D. London: Wakley and Son (1912) Ltd. 1925. (Med. 8vo, pp. 375-495; 1 full plate, 23 figures. Annual subscription, 22s. for volume of four parts; single numbers, 12s. 6d. each.)

³ *Die Krebskrankheit*. Ein Zyklus von Vorträgen herausgegeben von der Österreichischen Gesellschaft zur Erforschung und Bekämpfung der Krebskrankheiten. Wien: J. Springer, 1925. (Roy. 8vo, 110 pp., 85 figures. Paper cover, 30s.; bound, 35s.)

the practitioner wishes to be informed upon are entered on directly and without circumlocution.

The first few lectures are devoted to general subjects, such as the morphology and etiology of cancer, malignancy, the biochemistry of cancer, experimental tumour formation, and the problem of the frequency of cancer in the population; under the heading of experimental work will be found a discussion of the kindred subject of the Rous-sarcoma and the question of filterable viruses which has recently acquired a new significance from researches in this country. The remainder of the work deals with carcinoma as met with in the various organs and tissues of the body. Among the articles contributed special mention may be made of a very interesting account of the pre-cancerous stage in the skin, by Professor Kyrle, and of articles on the breast by Professor Fraenkel, the larynx by Professor Hajek, and the stomach by Professors Glaessner and Eiselsberg. The authors have amplified their lectures to some extent in order to render the descriptions complete, and a considerable number of illustrations have been introduced into the text.

FLORENCE NIGHTINGALE.

THE name of Florence Nightingale seizes the popular imagination as that of a sweet, gentle, and withal lovable woman. But when Sir Edward Cook published his *Life of Florence Nightingale* in 1913 a somewhat different picture was presented in his two exhaustive volumes. A woman of indefatigable energy, indomitable courage, and a fixed determination to have her own way, brooking no delay and attacking with purposeful sarcasm official opposition to her will, was portrayed. Much of this view of Florence Nightingale was subsequently made use of by Lytton Strachey in his *Eminent Victorians*, published in 1918, where a less agreeable picture of Florence Nightingale is drawn. It is probably on this account that it has been considered advisable to publish a shorter *Life* in the form of a revised and abridged edition of Sir Edward Cook's. The authoress, ROSALIND NASH, has compressed into some four hundred pages the two volumes of the original work, cutting and picking from them here and there in much the same way as Fitzgerald constructed his immortal verses from the *Rubáiyát* of Omar Khayyám. We cannot say, however, that Mrs. Nash's volume has anything like the same historical value as Sir Edward Cook's. It is a readable volume, but it leaves out too much. The part that is least compressed is that which deals with the Crimean war—in effect, that which presents to us the picture of the traditional "Lady of the Lamp" and the "Ministering Angel," and we are glad to have it; but much that is of intense interest in Florence Nightingale's correspondence is omitted, and the whole of that side of her character, brought out by her efforts at Indian reforms to which Sir E. Cook devotes a considerable portion of his second volume, is compressed into a dozen pages forming Part V, and a similar number of pages forming Chapter XI of Part III. In fact, the abridged edition devotes only one-third of the volume to Florence Nightingale's life and work after the Crimean war, although it was subsequent to 1855 that her real genius blossomed and her remarkable capacity for hard detail in effecting reforms in workhouse management, civil hospitals, and nursing, as well as in the army and army medical service, came into play. In describing Florence Nightingale's influence on the Red Cross movement, Sir E. Cook refers to Henri Dunant as a Swiss physician, and Mrs. Nash as a Swiss doctor. He was neither. He was a private gentleman and, to some extent at any rate, a company promoter; it was in this latter capacity that he found himself in the neighbourhood of Solferino at the time of the battle, if we may believe Professor François's *Berceau de la Croix Rouge*. Another curious mistake of which Mrs. Nash alone is guilty is the footnote on page 215, to the effect that Sir Thomas Longmore died in 1925 at the age of 97. He died in 1895 at the age of 79. Evidently the late Dr. Longhurst has been confused with him, although Dr. Longhurst's name does not appear in either

Sir E. Cook's or Mrs. Nash's volumes. An appendix of the latter's book deals with Lytton Strachey's "Florence Nightingale," which the authoress implies is the work of an entertaining caricaturist. Another appendix tells the reader how to make a "Nightingale."

NOTES ON BOOKS.

ONE of the most curious non-medical works we remember to have had for review is that entitled *Americana*.⁸ It is a collection of newspaper paragraphs and other short items of print, supplied by readers in every part of the United States during the past year, and arranged and annotated by Mr. H. L. MENCKEN, editor of the *American Mercury*. In a short preface Mr. Mencken explains the genesis and purpose of the extracts. "They come in part from newspapers of wide circulation and from other easily accessible sources, but they come in larger part from little country papers, from broadsides and other such documents of purely local circulation, and from handbills and other advertisements observed along the streets. They thus offer a singularly intimate and revelatory insight into the daily life and thought of the American people. . . . Here are the things that Americans of the vast majority read every day. Here are the ideas that are regularly presented to them." These four or five hundred samples of raw provincialism are grouped geographically according to the States, and illustrate, we must suppose, the mind as well as the speech of an ingenuous people—a people from whom have sprung such medical marvels as chiropractic and the Abrams box. "But (observes the editor) those who see only humour in these fantastic paragraphs see only half that is in them. Fundamentally, nine-tenths of them are serious in intent, and they are all presented here for a quite serious purpose. That purpose, one of the main aims of the *American Mercury*, is to make the enlightened minority of Americans familiar, by documentary evidence, with what is going on in the minds of the masses." He believes that no headway can be made in opposing and changing absurd and mischievous ideas until it is known clearly what they are; hence this book of "genuine home-brew." For the benefit of English readers a dryly humorous glossary has been appended, together with some caustic study notes for foreign students on the intellectual and moral standing of the several States. From these notes we learn, for example, that Delaware has no large city and no person of any consequence has lived in it for half a century; that good whisky is even cheaper in Florida than in New York; that one of the chief citizens of Kansas is a Mr. Howe, whose system teaches that wealth is the supreme good; that the climate of Louisiana is very hot and there are no inhabitants of any importance; that Mississippi has some of the worst newspapers in America; that primitive Washington has no citizens of any importance and is seldom heard from; with a good deal else to the same effect, only more so. It is rumoured that Mr. Mencken has in contemplation a volume of "Anglicana," but we doubt whether the choicest excerpts from our newspaper press could, in crudity of expression and artless vulgarity of thought, approach this amazing collection from America. Each extract is introduced with a line or two of editorial comment; thus, under the heading "Note on the training of a scientist from the Topeka Capital," we read: "Dr. M. F. Perkins, chiropractor, is now located in rooms 207-8 in the new Hotel Kansan. Before taking up the practice of chiropractic, Doctor Perkins operated a cleaning and pressing establishment at 727 Kansas avenue." Of professional interest also is the "follow-up letter employed upon ungrateful patients by a medical man of Paige, Texas," reproduced at page 238; and the dreadful end of "one Smith, a colored physician," burned to death by his white fellow citizens in the same State.

BALY'S *Spectroscopy*, Vol. I, is one of the series of text-books of physical chemistry produced under the editorship of Sir William Ramsay and Professor Donnan, a series designed to assist the development of those departments of research on matter in molecular dimensions which have been notable for their far-reaching and powerful influences on the growth of other branches of science. The third edition includes so much matter resulting from new investigation that it has been necessary to divide the work into two volumes. Volume I,⁹ which has recently been issued, recites the history of the subject and describes apparatus and methods of practice. Professor Baly is not only an experienced worker in the subject but an enthusiastic explorer of all that underlies the means of success in its investigation. It is easy to discern from his writing that he has gathered

⁸ *Americana*, 1925. Edited by H. L. Mencken. London: Martin Hopkinson and Co., Ltd. (Demy 8vo, pp. 309 + x. 7s. 6d.)

⁹ *Spectroscopy*. By E. C. C. Baly, C.B.E., M.Sc., F.R.S. In two volumes. Vol. I. Third edition. London and New York: Longmans, Green and Co. 1924. (Demy 8vo, pp. xi + 298; 138 figures. Vol. I, 15s. net.)

¹ *The Life of Florence Nightingale*. By Sir Edward Cook. Abridged and revised by Rosalind Nash. London: Macmillan and Co., Ltd. 1925. (Demy 8vo, pp. xi + 404; 2 plates. 15s. net.)

all the salient facts of history and he is well acquainted with the ingenious devices that have been employed to attain the objects desired in research. No less interesting is his account of the mechanical and optical qualities of instruments, his discursive comments on their development and the successes achieved by their use. Spectroscopy has become a very important agent of research in chemistry as well as in physics. It is destined to attract an increasing number of experimental workers, and there is no doubt that Baly's book will provide a most helpful foundation for their studies and a valuable companion in their labours.

Chemists have hitherto looked upon micro-methods of chemistry as a necessity imposed only by scarcity of material; we were accordingly surprised to read the advertisement on the wrapper of *Practical Chemistry by Micro-Methods*¹⁰ that the particular recommendation of the book was a saving of 50 per cent. in the cost of experiment. Perusal of the volume appeared indeed to reveal no other merit, for the instruction given simply follows that of an ordinary elementary textbook on practical chemistry, with directions to use a diminutive Bunsen burner and diminutive quantities of materials and reagents. We have looked in vain for instruction that would enable a student to perform effective experiments with smaller quantities than those hitherto considered necessary to success. All that we have noted is a disregard of that form of experiment which for due performance requires more than a drop of reagent. In the preface the author pleads that students having other subjects to learn are obliged to waste too much time on practical chemistry. We recognize the difficulty, but the author's hope of avoiding waste of time by the use of minute amounts of material seems to us to be misplaced. We should have objected less to a method of saving the student's time by making him the spectator of experiments performed by an experienced worker. Can it be conceived that power of adaptation has been dormant among teachers of chemistry for nearly a hundred years and that there has been no evolutionary tendency towards the standardization of the student's test tube and crucible? We have, in fact, no doubt that the use of moderate quantities of stuff is of more educational value and serves better as an introduction to methods of manipulating smaller quantities when later the necessity arises. Our criticism is aimed solely at the title and the author's standpoint regarding the foundation of teaching practical chemistry. The book contains excellent and useful matter, and as an adjunct to the student's equipment for the elementary study of practical chemistry it will prove helpful. We appreciate the description of dry tests and reactions so often omitted from modern courses of instruction, and we like greatly the author's excursions into matters having special interest for medical students.

Nova et Vetera.

CHEMISTRY OF THE ANCIENT ASSYRIANS.

ONCE more Professor Campbell Thompson has given to the Assyrian scholastic world an exceedingly interesting book upon a very special branch of the study.¹ It is needless to say that tablets bearing upon chemical matters in Assyrian literature are exceedingly rare, and even the texts in the Assyrian wedge-writing published in this work can hardly be described as chemical works in the true sense of the word.

As is commonly the case in the ruined libraries of Babylonia and Assyria, the clay documents they contained have suffered greatly in the course of their long burial in the soil. The clay fragments now published by the author number twenty-four. They were found in the library of Assur-bani-pal, and are now preserved in the British Museum. Prominent in their contents is the manner of making glazes, glass, and the colour with which they were stained. As is usual, the production of these things was associated with certain magical formulae. The oven had to be begun in a favourable month, and on a fortunate day, sacrifices had to be made, and logs of styrax (?) prepared for kindling the furnace.

According to the formula given, the method of making what is regarded as blue glaze was a mixture of 10 *mana* of sand, 15 *mana* of saltpetre, and $1\frac{1}{2}$ *mana* of styrax-gum.

¹⁰ *Practical Chemistry by Micro-Methods*. By Egerton Charles Grey, D.Sc., F.I.C., M.R.C.S. Cambridge: W. Heffer and Sons, Ltd. 1925. (Demy Bro., pp. ix + 124; 16 figures. 4s. 6d. net.)

¹ *On the Chemistry of the Ancient Assyrians*. By R. Campbell Thompson, M.A., D.Litt., F.S.A., Fellow of Merton College, Oxford. London: Luzac and Co. 1925. Price £2 2s.

Directions for mixing are given. As this is a recipe for making what the Assyrians called *uknū ēbbu*, "lapis lazuli," it is clear that it was not the stone, but a glaze imitating it, such as was used so plentifully in the decorations of Nebuchadnezzar's palace.

It would be interesting to quote here all the recipes for making glass, but the space at our disposal would not suffice. Of special note are Professor Campbell Thompson's researches with regard to arsenic. He argues that the various forms in which it was used are represented by the Sumerian compound groups *ASH-GE-GE*, *ASH-KHAR*, *SHIM-BI-GUSUKIN*, *SHIM-BI-ZIDA-SIGSIG*, and *SHIM-BI-IGI-GUNNU*. One of the keys to the meaning "arsenic" is apparently furnished by the Semitic rendering of *SHIM-BI-ZIDA*—namely, *gukhlu* and *amamū*, the former, as recognized by Professor H. Zimmern, for *gukhlu*, the Arabic *kohl*, "collyrium." (If these words are the same, the Arabic form is not well transcribed, as it has *k* for *q* or *g*, and *h* for *kh*.) How *zida*, "lasting" or "true," is to be understood in this compound is not clear; but in the variant longer compound, *SHIM-BI-GUSUKIN*, which is rendered by the Semitic *shindu*, or, possibly (if we restore *SHIM* at the beginning of a damaged line), as *shindu khuraqu*, "paint, gold," seems to furnish the key. This the author has identified with orpiment—*auri pigmentum*, the yellow trisulphide of arsenic. Other renderings of this and of *SHIM-BI-SIGSIG* in Assyrian are *lêru* and *shpu*, which might be translated (if this rendering be correct) by "very yellow paint." Owing to the common meaning of *sic* as "yellow," in Assyrian *argu*, he is inclined to render the Sumerian *SHIM-BI-SIGSIG* as *shindu argu*, "yellow paint," as before, and regard it as the origin of the word *sandarach*. Time alone will show whether this etymology is right.

Another attractive section is No. 25, which deals with the Assyrian *khulalu*, belonging, so the author thinks, to the category of colours. This word, he reasons, is that used for "white lead," whilst another word, *sasu*, translating the same Sumerian group with an additional character, stands for "red lead." The strange thing about these products is that they are classed as stones, but one naturally asks what other determinative prefix, in a script poor in such aids to interpretation, could be applied to them. The medicinal use of white lead, however, is a difficulty, even though "given in small doses as a sedative." The author contends, however, that his conclusion that *khulalu* is "white lead" is confirmed by the fact that this list has also the expression *khulalu ini*, "*khulalu* of the eye," and that it is mentioned in the medical texts. When I was preparing the list giving the various kinds of *khulalu* for publication in the fifth volume of the *Cuneiform Inscriptions of Western Asia*, I thought *khulalu ini* was *kohl*, but clearly this supposition was wrong.

Interesting in the extreme is the way in which magnetic haematite was indicated. The word in question, a compound, was *tak ka-gina-dibba*, and was translated in Assyrian by *shadanu qabitu*, "grasping haematite," because it "seized" any piece of iron brought near it.

The transcription of the Sumerian word or sign used as a prefix for stones is indicated by *tak*, but we are in doubt as to whether this was one of the names for "stone" or not. One thing, however, seems to be certain, and that is, that three other words were so rendered—namely, *i*, *na* (used for stone which had been worked), and *gi*. The first and last probably designated glazes and glass, and manufactured materials of a stone-like appearance.

These are only some of the questions treated of in this noteworthy book. Many other things are mentioned in the principal index, such as the embryo, the magnet, the mill for grinding lapis, the mirror, etc. References to ancient and modern authorities are numerous, and the indexes are very useful. The list of Sumerian and Akkadian words, however, would have been much more useful if indications of their meanings had been given in every case. The reproduction by mechanical means from typewritten pages, also, leaves much to be desired, as the print is often exceedingly faint and imperfect. Would typographic printing, at present so very dear, have placed this useful work beyond the reach of the ordinary purchaser? Another great advantage would have been the reduction of the book to a quarter of its present size, or less.

T. G. PINCHES.

British Medical Journal.

SATURDAY, JANUARY 2ND, 1926.

THE BRITISH PHARMACOPOEIA.

THE remarks of the President of the General Medical Council in his address at the opening of the autumn session¹ informing the profession that the preparation of a new edition of the *British Pharmacopoeia* has been begun, and the coming into effect of a new revision—the tenth—of the *United States Pharmacopoeia*, have afforded Dr. A. J. Clark, Professor of Pharmacology in University College, London, an opportunity of discussing the aims of a national pharmacopoeia and the method by which they should be attained, in an article which is published elsewhere in this issue (p. 30). In it he institutes a comparison between the two pharmacopoeias, not altogether to the advantage of our own.

The Medical Act of 1858 imposed upon the General Medical Council the duty of causing to be published under its direction a book "containing a list of medicines and compounds, and the manner of preparing them, and such other matters relating thereto as the General Council shall think fit." The book was to be called the *British Pharmacopoeia*, and the Council was to alter, amend, and republish it as often as it deemed necessary. A subsequent Act (1862) directed that this *Pharmacopoeia* was to be substituted for the pharmacopoeias of London, Edinburgh, and Dublin. The first *British Pharmacopoeia* was published in 1864, the second in 1867, and an addendum to it in 1874; a third *Pharmacopoeia* was issued in 1885, and an addendum to it in 1890; a fourth *Pharmacopoeia* was issued in 1898, and an Indian and Colonial addendum in 1900. The *Pharmacopoeia* now current is the fifth, and in it the material about the Indian and Colonial drugs, which had been prepared for the addendum of 1900, was included in the text so far as seemed advisable, so that the Council claimed to have produced "a *British Pharmacopoeia* suitable for the whole Empire." This is a point upon which Sir Donald MacAlister has on more than one occasion laid stress, and he has observed also that it is expedient that in different countries the same or equivalent names, especially in the case of potent drugs, shall mean preparations of equivalent strength and composition. In order to obtain uniformity two international conferences have been held in Brussels—the first in 1902 and the second last September. This second conference advised the recognition of biological methods of standardization which have been, or may be, recommended by the Health Section of the League of Nations, and approved various steps towards the unification of pharmacopoeias.

In the *Pharmacopoeia* of 1885 an endeavour was made to fix the alkaloidal strength of some of the tinctures, and in that of 1898 the amount of the more important alkaloid, or of total alkaloid which ought to be present, was specified. This policy was pursued and extended in the *Pharmacopoeia* of 1914, and the number of drugs of definite chemical composition to which assayed processes were to be applied was increased. The Council consulted the universities and medical corporations as to additions and omissions,

and was aided by some independent inquiries as to the frequency with which the official preparations had been actually prescribed in different localities. It had a conference with delegates nominated by the pharmaceutical societies of the United Kingdom, and appointed a committee of reference in pharmacy, consisting of persons nominated by those societies. The committee presented a number of reports and recommendations, which were published for the information of medical practitioners and pharmacists. The Council also set up a committee of reference in chemistry, and, in response to official inquiries transmitted by the Colonial Office and the India Office to Governments and administrations of the Empire, it received a number of suggestions from medical and pharmaceutical authorities overseas; all the information and criticisms thus collected were submitted to those engaged in the preparation of the *Pharmacopoeia* of 1914, which was carried out under the general supervision of the *Pharmacopoeia* Committee of the Council.

The *United States Pharmacopoeia*, of which the tenth edition came into force on the first day of this year, dates back to a suggestion made by Dr. Lyman Spalding of New York in January, 1817. The first *National Pharmacopoeia*, prepared by a committee of which Dr. Spalding was chairman, was issued at the end of 1820, and since then the *Pharmacopoeia* has been revised every ten years. The duty of revision is entrusted to a corporate body, the *United States Pharmacopoeial Convention*, with no direct Government affiliation, but each new revision, when it appears, is adopted by the *United States Government* as the official standard for medicines. When it was decided to proceed with the revision which has just come into force the first step was to call a meeting of the Convention. This was held at Washington in 1920; it was attended by representatives of the Government services, by delegates of national organizations, including the *American Medical Association*, the *American Pharmaceutical Association*, and the *American Chemical Society*, and by representatives of universities and medical and pharmaceutical bodies in the several States. The object of the *Pharmacopoeia* is defined as the provision of standards for drugs "sufficiently used in medical practice throughout the *United States* and its possessions, to lay down tests for the identity, quality and purity of these," and "to insure, so far as possible, uniformity in physical properties and active constituents." The Convention recognized that the international conference for the unification of formulas for potent remedies had performed a signal service for all countries by recommending the various pharmacopoeias of the world to adopt certain standards for potent medicines, and advised that the standards, wherever practicable, should be retained or adopted in the revision; it was, however, also recognized that the advances in science since the international conference at Brussels in 1902 rendered the standards then adopted not such as could now be approved as in conformity with present knowledge and ideals. The Convention appointed a general committee of revision, which was divided into fifteen subcommittees, and the chairmen of these committees formed an executive committee. The first of the committees was on scope, and decided upon admissions and deletions; it was composed of sixteen physicians and five pharmacists. The physicians were responsible for finally deciding about therapeutically active substances, the pharmacists for those which were pharmaceutical necessities. The decisions were published, and all criticisms were

¹ SUPPLEMENT, November 28th, 1925, p. 187.

collected and referred to a referee committee of physicians on scope. The definition of the objects the revisers of the *United States Pharmacopoeia* were to have in view has just been quoted. That before the *British Pharmacopoeia* Committee is "to afford to the members of the medical profession and to those engaged in the preparation of medicines throughout the British Empire one uniform standard and guide, whereby the nature and composition of substances to be used in medicine may be ascertained and determined." The American definition is perhaps the more explanatory and precise, but it need not be doubted that the aim of those to whom the task of revising the *Pharmacopoeia* in each country was, or is, committed is the same. The American executive committee had altogether, as has been said, fifteen subcommittees, including one on biological products and diagnostical tests, and another on biological assays.

With these few explanatory notes, mainly of an historical nature, we leave Professor Clark's essay to the judgement of our readers, with only one observation. He evidently considers that the method pursued in the *United States* is the more thorough, and believes that the British committee might exercise its authority more drastically to reduce the number of drugs and to lessen the number of preparations made from them, and be more courageous in admitting only effective standardized preparations of potent drugs, being guided in the choice of the preparations not merely by the custom of the profession but by the advances that have been made in pharmacology.

SPECIFIC SERUM TREATMENT OF SCARLET FEVER.

THE paper we publish to-day by Dr. Gardner Robb of Belfast (p. 11) may be looked upon as among the first-fruits of the labours of a group of pathologists, whose investigations into the nature of scarlet fever now promise a profitable reward to the clinician. Here is also another example of the fact that the fortunes of pathology and therapeutics are most intimately bound together, each benefiting by the vitality of the other; for, in the case of scarlet fever, a more enlightened pathology has been followed almost immediately by a more effective therapy. This is very apparent when we bring to mind the main events in the history of research work on scarlet fever during the last few years—a story well worth recalling.

The forward movement dates from 1917, when Schultz and Charlton observed that on injecting a few drops of the serum from a convalescent case of scarlet fever into the skin of patients during the acute stage, the rash faded at the spot. A similar power of blanching the scarlet fever rash was found to be present in the serum of some, but not all, healthy individuals. These observations, which excited little comment at the time, were destined to play an important part in subsequent history, for they gave movement and direction to scarlet fever research. A group of bacteriologists began an intensive study of scarlet fever; the most successful were Drs. George and Gladys Dick, who in 1923 furnished evidence that the infecting agent in scarlet fever is a haemolytic streptococcus. They succeeded in isolating this germ from the throats of scarlet fever patients and in propagating it in pure culture, and they reproduced the disease scarlet fever by inoculating human volunteers with their cultures. This particular haemolytic streptococcus, which could be distinguished from kindred

cocci by serological tests, produced a filterable toxin when growing in broth culture. On the basis of these observations it was possible to found a rational conception of the pathology of scarlet fever—namely, that the disease is caused by infection with the haemolytic scarlet fever streptococcus, and that the symptoms of the disease and characteristic rash are due to toxin manufactured by the germ. The blanching reaction of Schultz and Charlton found an explanation in the hypothesis that the serum of convalescent patients contained an antitoxin able to neutralize the circulating toxin locally.

This new pathological view quickly brought practical benefit to clinical medicine, in the Dick test for diagnosis and the antitoxin treatment of scarlet fever. The diagnostic value of the Dick test is now being examined in many parts of the world. We have so often referred to it that it is enough to remark here that most of the evidence offered has been favourable to the test. Perhaps the most recent expression of opinion is from three Russian doctors who write from Moscow, and seem very satisfied with the practical value of the test.¹ The antitoxin treatment of scarlet fever has recently been the subject of two important papers—one by the Drs. Dick, entitled "Therapeutic results with concentrated scarlet fever antitoxin," which was published in the *Journal of the American Medical Association* for November 28th, 1925; the other is that by Dr. Robb which we publish to-day. These, and earlier papers on the specific therapy of scarlet fever, are full of promise of a more successful treatment of this infection. They also raise two problems which demand further study—namely, the best methods for producing and standardizing the antitoxin.

The Dicks appear to have been successful in their first attempts at treating scarlet fever with antitoxin. They took 100 patients with scarlet fever, and gave antitoxin to the 50 more severe cases and kept the 50 less severe as controls. Complications due to scarlet fever occurred in 19 of the control cases and in only 4 of the antitoxin series; the conclusion seemed justified that antitoxin treatment had shortened the course of the disease and reduced the number and severity of complications and sequelae. The results were substantially the same in Dr. Robb's series. In the 100 cases available for review he found the incidence of complications exceedingly low. Severe cervical adenitis, late nephritis, and purulent nasal discharge were absent from all cases. The Dicks also noticed that no post-scarlatinal nephritis occurred when antitoxin was given early.

We agree that the statistical study of the incidence of complications in cases which have or have not received antitoxin is likely to prove the most convenient way of assessing the value of this form of treatment. As the present form of the disease is mild, having a mortality rate of less than 4 per cent., a very large number of cases would have to be treated before evidence could be derived from the actual mortality rates. But besides the statistical evidence concerning complications—which, as we have seen, is very favourable—the Drs. Dick and Dr. Robb also speak enthusiastically of immediate clinical evidence pointing to the efficacy of the serum—disappearance of the rash, fall of temperature, and improvement in the general condition. Dr. Robb, however, does not place so much reliance on fall of temperature as do the American workers, because quick changes in the temperature chart are common after any form of serum; but he says: "As a rule the temperature was down to

¹ *Journ. Amer. Med. Assoc.*, November 28th, 1925, p. 1728.

normal, and stayed there, in twelve to forty-eight hours after the administration of the serum." On the other hand, the Dicks have always laid particular emphasis on the disappearance of the rash as a convenient indicator of the action of antitoxin. In their recent paper (*loc. cit.*, p. 1694) they remark: "If enough antitoxin has been given the rash will be definitely faded within twenty-four hours, and there will be a marked improvement in the general condition of the patient, especially noticeable in the most toxic cases." Dr. W. H. Park of New York, who took part in the discussion of this paper by the Drs. Dick, said, among other things: "A very toxic patient, after an intravenous injection, will often appear convalescent in six hours if he has no complications."

These encouraging results must not be allowed to conceal the fact that the methods of production and standardization of this antitoxin rest on a foundation far less secure than exists, for instance, for diphtheria antitoxin, and until they are improved it will be difficult for manufacturers to ensure a standardized and dependable product. It may not prove difficult to settle the best method of producing the antitoxin: besides the method of Dochez, described by Dr. Robb, there are two other methods for which good results are claimed. The Drs. Dick use sterile filtrates of streptococcus cultures for producing antitoxin, and inoculate horses subcutaneously with increasing doses of sterile toxin. They lay great stress on the importance of selecting a good toxin-producing strain of streptococcus for the preparation of toxin; by their method they produce a powerful antitoxic serum. Certain commercial firms are now making a serum by injecting living cultures of streptococci as well as sterile toxin, and thereby offer a serum for which both bactericidal and antitoxic properties are claimed. Laboratory and clinical experience may be relied on to decide between the merits of these different products.

A greater difficulty is presented by standardization. Hitherto the antitoxic power of the serum has been tested on human volunteers. The strength of the scarlet fever antitoxin has been measured by the power of the product to neutralize scarlet fever toxin as judged by the Schultz-Charlton reaction in early cases, or after injection of scarlet fever toxin intradermally into susceptible individuals: 1 c.cm. of serum should neutralize at least 1,000 skin-test doses of toxin. The Dicks found that 1,000 skin-test doses of toxin is capable of producing transient symptoms of mild scarlet fever in susceptible adults. An amount of antitoxin sufficient to neutralize twenty times this quantity of toxin has been found to be an effective therapeutic dose. The American workers consider that it is wiser to avoid the mention of units other than skin-test doses so as to avoid confusion between scarlet fever and diphtheria. The latest improvement in the mode of preparation of the serum consists in the concentration which can be effected by methods similar to those employed for diphtheria antitoxin. This reduces the size of the dose, increases its potency, and, by reason of the lessened protein, diminishes the frequency and degree of serum sickness. The discovery of a more accurate method of estimating the potency of scarlet fever toxin and antitoxin would be a valuable addition to what has already been accomplished.

—♦—
We much regret to announce the death, on the evening of Monday, December 28th, of Dame Louisa Aldrich-Blake, D.B.E., M.S., M.D., Dean of the London School of Medicine for Women and consulting surgeon to the Royal Free Hospital. We hope to publish a memoir in our next issue.

EIGHTY YEARS AGO.

WE are indebted to Dr. Frederick W. Cock for being at the pains to send us a pamphlet he found recently among some old papers in his house at Appledore in Kent. It contains a report of the second annual meeting of the South-Eastern Branch of the Provincial Medical and Surgical Association. Though containing nothing of first-rate importance, it is of real interest as illustrating the stage to which organization of the profession had attained eighty years ago. The meeting was held at Ashford, Kent, on June 24th, 1846, and Dr. Sibbald of Maidstone presided over a gathering of twenty-six members, the total membership of the Branch being ninety-eight. His address was devoted to the fifth of the five objects of the parent body—"The maintenance of the honour and respectability of the profession generally in the provinces" by friendly intercourse and free communication. The wording is a little different, but the meaning is the same to-day. The profession, he held, was improving its position in the State; more deference was being paid to its opinions and more regard to its interests. Parliament had passed an Act recommending magistrates to afford retiring pensions to officers of county asylums, and on a scale of liberality which evinced appreciation of their services; also the cost of treatment of paupers was to be in part charged to the Consolidated Fund, so that medical officers of unions would be more independent of boards of guardians. A matter discussed at the Ashford meeting recalls or reveals a position regarding medical examination for life insurance which can hardly be even a memory in the present day. It appears that insurance offices required opinions and confidential statements by individual men regarding the health of their patients, and most offices refused to pay any fee for such information; at the same time the confidential character of the report was frequently infringed. It is not surprising that in these circumstances the Branch passed a resolution that insurance offices had no claim whatever on the private medical attendant for an opinion regarding an applicant, and that every office should appoint medical referees of its own. The resolution was to be sent to all life assurance offices. In the committee's report reference is made to the working machinery of the parent Association. Its annual meetings had usually been held in the great towns of the north and west, practically inaccessible to members in Kent, so that it was only the establishment of the Branch that had brought about medical gatherings; even Branch meetings then involved time and outlay which would now be sadly grudged. Railways were only in their infancy, but the hope was expressed that with their aid members would be enabled to attend the annual Branch meeting and get home again in the course of a day, or at the most within twenty-four hours. A proposal that the South-Eastern Branch should, by agreement with the Southern Branch, be extended so as to embrace the whole of the counties of Surrey and Sussex, as well as the whole of Kent, was under consideration; this was regarded as "a very convenient territorial arrangement." Nowadays these three counties include some seventeen Divisions, each with its own meetings. Dr. Sibbald, in his address, made a passing reference to a "contemplated measure for the improvement of the health of towns" introduced in the previous session of Parliament, but deferred owing to the state of public business. This reference brings to mind the fact that the labours of Chadwick, Southwood Smith, and their colleagues, as set forth in the epoch-making report of 1842, were in course of bringing forth fruit of inestimable value for the national welfare. A Royal Commission was appointed in 1842, and presented a report in 1844 and another in 1845. The Commission, besides hearing some witnesses, made inquiry into the health conditions of each of fifty towns, and proposed new legislative measures

applicable to all towns and populous places. Several enactments, indeed, were required to cover the scheme, and these culminated in the Public Health Act of 1848. It was very fortunate both for the public health and for the interests of the medical profession that, simultaneously with this public legislation, the Provincial Medical and Surgical Association was arranging its own affairs, and organizing itself for the advancement of medical science in its various branches, for encouraging harmony and good feeling among its members, and for maintaining the honour of the profession. As every reader of the *BRITISH MEDICAL JOURNAL* knows, or ought to know, the Provincial Medical and Surgical Association became the British Medical Association in 1856. Its membership, which in 1846 was just over 1,800, is now more than 30,500.

ENGLISH-SPEAKING PIONEERS IN TROPICAL MEDICINE AND HYGIENE.

PRESIDENTIAL addresses usually deal with the present and the future, but there is not only an attractive atmosphere but a stimulating value about a retrospective review of the subject with which the audience is concerned. This has been convincingly proved by the address of Dr. Andrew Balfour, director of the London School of Hygiene and Tropical Medicine, in his presidential address to the Royal Society of Tropical Medicine and Hygiene on "Some British and American pioneers in tropical medicine and hygiene."¹ Few men are so well fitted by experience and literary skill to praise these famous men who begat tropical medicine and hygiene, but he has presented in chronological order a Valhalla of over seventy sketches of those who should be held in grateful remembrance for work often done in most difficult circumstances—a lesson calling not only for admiration, but for modesty on our part. Some of these are thus rescued from undeserved oblivion. This address is made the more interesting by the portraits of fifty men and three women, Florence Nightingale, Mary Kingsley, and Mary Slessor, the missionary for thirty-nine years in Nigeria, where she was known as "Ma Akamba" (the great mother). She put a stop to infanticide, and was a remarkable pioneer in hygiene through her strange influence on the native. Dr. Balfour walks, as it were, through his picture gallery giving thumb-nail sketches of those on the walls, interpreting the physiognomy of those long gone and adding personal touches to the moderns whom he has met in his twenty-five years of wandering work. Beginning with the great army physician, Sir John Pringle (1707-1783), he ends with the greatest of them all, Sir Patrick Manson, "the father of the modern science of tropical medicine," as the great Frenchman, Raphael Blanchard, first acclaimed him. Both these pioneers in the gallery were Scots, and so are many in between: James Lind, Gilbert Blane, Donald, son of Monro *primus*, William Wright, James McGrigor, James Randall Martin—"from the misty Isle of Skye," of whom there are two portraits—George Ballingall, Morehead, Bidie, David Livingstone, W. A. F. Browne, D. D. Cunningham, William MacGregor, Governor finally of Queensland, George Lamb, and Andrew Davidson. Among the American pioneers are Benjamin Rush, of Quaker stock, who first described dengue; J. C. Nott of South Carolina, who in 1846 suggested that mosquitos might be responsible for the spread of yellow fever; C. J. Finlay and Walter Reed, also pioneers in connexion with "yellow jack"; H. R. Carter; W. C. Gorgas, on whose coffin, when borne up the aisle of St. Paul's in 1920, the only wreath was most fittingly that of Sir Patrick Manson, who was so soon to follow him on that journey from which no traveller returns; and S. T. Darling (1872-1925), the outstanding tropical parasitologist

and pathologist, who was a fellow prisoner in the quarantine station at Colon in 1914; and Howard Ricketts. Dr. Balfour modestly reproaches himself for having said little about lay pioneers, such as Chadwick, Joseph Chamberlain, Alfred Jones, Baird Smith, and T. E. Demster, who in 1848 introduced "the splenic index." No one who reads this charming address can have any feeling but the wish to hear more on the same lines, and if he really feels penitent the remedy is at hand for Dr. Balfour to give his readers a full account of what men other than medical practitioners have done for tropical medicine and hygiene.

RHEUMATIC HEART DISEASE IN CHILDREN.

THE appeal by the chairman and other honorary officers of the Invalid Children's Aid Association for £10,000 with which to equip a home to accommodate children suffering from rheumatic heart trouble in its early stages is so modest, and the cause so good, that we feel justified in hoping that it may speedily be successful. The need for treatment in hospitals and convalescent homes in the early stages of heart trouble in children was clearly stated in the discussion on the subject at the Bath meeting and in our leading article on October 31st, 1925. In no disease and in no circumstances is the maxim "*Principiis obsta*" more applicable. To allow the child convalescent from an acute attack of rheumatic heart disease to return from hospital direct to what in many cases is a poor home, and in nearly all one where proper after-care cannot be carried out, is to court disaster. The Invalid Children's Aid Association has for several years been carrying on homes for such cases at Willesden and at Hartfield in Sussex, but the lease of the latter terminates next year, and it is for the purpose of re-establishing this home elsewhere that the appeal is made. The damage done by acute rheumatism in this country is enormous. One of the openers of the discussion at Bath, Dr. Askins, who is the deputy medical officer of health for the city of Bristol, estimated the annual loss of life from rheumatic heart disease as between 12,000 and 18,000. If much impression is to be made on such a mass of suffering as is implied by these figures, the homes at Willesden and Hartfield must be multiplied many times; they represent a beginning, and offer a demonstration to the public of the saving of health and life which early after-care can secure. Some of the speakers at Bath deprecated the view that poverty was an important factor in causation, but we understand that an inquiry into the after-histories of children who had been treated for rheumatic affections in a London hospital brought out with striking clearness the fact that a poor home is a very important factor in estimating the chances of recovery. The home surroundings of every case were inquired into by experienced social workers, who visited the homes and inquired closely into every circumstance of hygienic importance; the conditions were thus ascertained with a very much greater degree of accuracy than could be attained by judging from the appearance of the patients or their friends at the hospital. Probably it will hardly be denied that this form of disease is far commoner in the working classes than in those who are better endowed with this world's goods, and that, like consumption, the incidence of acute rheumatism in childhood diminishes as we ascend the social scale. Not only is actual penury to blame for furnishing a congenial soil for the seeds of these diseases, but unfortunately it too often appears as if the less the family income the less wisdom is shown in laying it out, so that the money, which is little enough to provide the most nutritious plain food, is spent on innutritious trifles—to say nothing of alcoholic drinks. Doubtless improved housing and nutrition, in whatever way they were brought about, would have a great effect on the prevalence of acute rheumatism, as of other diseases.

¹ Balfour, A.: *Trans. Roy. Soc. Trop. Med. and Hyg.*, London, 1925, xix, 183-229.

PHYSIOLOGICAL ACTION OF LIGHT.

As one of the course of lectures and demonstrations now being given at the James Mackenzie Institute for Clinical Research, St. Andrews, Sir James Irvine, F.R.S., Principal of the University, recently delivered an address on the effect of light on chemical and physiological processes. After a general review of research methods as applied to a large variety of problems ranging from engineering to biology, he said that, irrespective of the nature of the problems concerned, a common feature which emerged was that fundamental researches were concentrated on the study of units. The electron and the atom became the pursuit of the physicist, the molecule of the chemist, and the cell of the biologist. It was a matter of extreme difficulty in the present state of knowledge to apply such principles to clinical medicine, but there appeared to be ample justification for studying more minutely the effects produced by light energy. That the action of light on the human body was important had long been known, and was now beginning to be fully appreciated. Taking examples chosen from well standardized chemical reactions, he showed that activation by light was dependent on a specific wave-length (which could be measured accurately), and, further, that such reactions could be catalysed by reagents capable of transforming wave-lengths. Discussing the clinical value of irradiation, Sir James Irvine drew a parallel between its effects and those induced by certain vitamins, particularly fat-soluble A, and gave an account of the recent work by Zilva, Drummond, and others on the activation of various materials by light. The conclusion he drew was that the photocatalysis of the reactions concerned in metabolism was possible only within a limited range of wave-length. This consideration might be applied extensively to biochemical studies, and the clinical observer could contribute supplementary evidence of the utmost value.

RECENT ADVANCES IN NEUROLOGY.

Dr. R. Ley has contributed to the *Bruzelles-Médical* for December 6th, 1925, a sketch of the progress in neurology during the past couple of years. He discusses first the similarity, if not identity, that has been established between the virus of encephalitis lethargica and that of herpes, to which frequent reference has been made in our *Epitome* paragraphs. Dr. Ley thinks that the comparative frequency of the one condition and the rarity of the other are due to a weakness of personal resistance and an exaltation of the virulence, which combination only rarely occurs. He draws attention to the protean nature of the symptoms of syphilis of the nervous system, encephalitis lethargica, ponto-cerebellar tumours, poliomyelitis, and tuberculous meningitis being among the diseases simulated. Treatment should be intensive, varied, and prolonged. Dr. Ley finds that the best results are obtained by combining a course of intravenous injections of arsenobenzol with intramuscular injections of bismuth, mercurial injections being also given from time to time. In true epilepsy with convulsive attacks it has been shown by Bigwood that the acid-base equilibrium of the blood is profoundly altered; the blood plasma is always alkaline before the attacks, with a return to the normal, or even an acidosis, after the crisis. The alkalinity is associated with diminution of the calcium ions in the blood plasma, which may be correlated with the known physiological action of calcium on the excitability of the neuro-muscular system. This suggests that treatment should take the form of the production of acidosis, as, for example, by fasting, or the administration of dilute hydrochloric acid, which has been known to prevent the development of the convulsive crisis. According to Dr. Ley, boro-tartrates and gardénal also seem to act by producing acidosis. Ventricular puncture has been recommended for the introduction of drugs, especially of anti-

meningococcic serum (2 to 5 c.cm.) into the ventricles by the trans-cerebro-frontal route suggested by Sicard. Suboccipital puncture has been used in both diagnosis and treatment, while cervical puncture is of value in localizing medullary tumours, the cerebro-spinal fluid being found normal above, but altered below, the level of the tumour. Radiotherapy has made rapid strides in the treatment of cerebral tumours in the region of the hypophysis, though in the case of tumours elsewhere the results have been less favourable. This contrast is attributed to the polymorphic character of gliomas, their variable radio-sensitivity, and the differences they present as regards necrosis *en masse*, or of the more or less rapid absorption of their toxic products.

THE CONTROL OF MOSQUITOS IN SAMOA.

It has been known for some years that *Aedes variegatus*, or *Stegomyia pseudoscutellaris*, as was its former denomination, was the carrier of filariasis in Samoa. Dr. P. A. Buxton, who went there on an expedition from the London School of Hygiene and Tropical Medicine, and is now on his way back to take up the duties of director of the entomological department at the school, has done good service in once more calling attention to the breeding places of this disease-carrying insect.¹ The ordinary measures—guarding against unscreened cisterns, repairing sagging gutters, removing empty tins, and improving scavenging methods generally—will not suffice for its eradication. Fruitful sources, often overlooked, are rot-holes in trees which are pollarded and used as fence-posts, and the steps cut in the trunks of cokernut palms. His report also deals with antimosquito measures directed to reducing other more irritating and virulent biters, though not vectors of human disease in Samoa—namely, *Culex fatigans* and *Finlaya kochi*. Screening the ventilators of septic tanks and the regular monthly treatment of pit privies with cresol would deprive the former of their favourite breeding sites. Lowering by a couple of feet or so the water level of the Taufusi swamp, and thus reducing the amount of taro grown, would to a large extent control the latter. Dr. Buxton sounds a timely warning against the potential danger of this swamp should *Anopheles* be introduced, say, from the New Hebrides or Solomon Islands, when an epidemic might arise like that which devastated Mauritius a little more than half a century ago, killing over 32,000 persons in two years and making Port Louis a veritable city of the dead.

MIDDLESEX HOSPITAL PRESS COMMITTEE.

The Press Committee of the Middlesex Hospital has been for some time actively engaged in educating the public by means of health leaflets, and on February 16th, 1924 (p. 305), we referred to the first seven of the series which were then in circulation. Two more have now been added, dealing respectively with eye-strain and the precautions to be observed by tuberculous patients, and in the committee's annual report it is stated that other leaflets are contemplated. During the last year over 36,000 leaflets have been supplied to the medical officers of health of various large towns and counties. Besides this useful activity the Press Committee hopes later on to guarantee against loss up to a certain amount any author publishing a book under its auspices, or, alternatively, is willing to contribute towards the cost of publication of such a book. The funds so far received have been inadequate for this purpose, but one-third of the cost of the publication of the report on *Cancer Research at the Middlesex Hospital from 1900 to 1924* was provided through the committee, which also assists in the publication of textbooks produced by three or more members of the hospital staff.

¹ Mandated Territory of Western Samoa. Annual Report of the Department of Health for the year ended March 31st, 1925. Appendix D: The Control of Mosquitoes in Apia, Samoa. By P. A. Buxton, M.R.C.S., L.R.C.P., D.T.M. and H.

THE COMPILATION OF PHARMACOPOEIAS:

INCLUDING A COMPARISON OF THE UNITED
STATES AND THE BRITISH.

BY

A. J. CLARK, M.D.,

PROFESSOR OF PHARMACOLOGY, UNIVERSITY COLLEGE, LONDON.

THE tenth revision of the *United States Pharmacopoeia* was completed in 1925, and the new edition came into force on January 1st, 1926.

A revision of the *British Pharmacopoeia* has just been commenced, and therefore it is interesting to compare the new *United States Pharmacopoeia* (U.S.P. X) with the current B.P., which appeared in 1914, in order to see what changes appear desirable in the latter volume.

When comparing the two it is, of course, necessary to remember that the B.P. is twelve years old, and that great advances in therapeutics have occurred since its appearance. On the other hand, it must not be forgotten that the present edition of the B.P. is still, and will continue for a year or two to be, our official guide for the preparation of drugs, and therefore if it is found to be very out of date this fact, whatever be its cause, is a strong argument for making some change that will enable our pharmacopoeia to keep more in touch with existing medical practice.

In considering the merits of any book it is necessary to have a clear idea of the purposes which it is intended to serve. Fortunately these purposes have been defined, since in the preface to the current *British Pharmacopoeia* (p. viii) it is stated that its object is "to afford to the members of the Medical Profession and to those engaged in the preparation of medicines throughout the British Empire one uniform standard and guide whereby the nature and composition of substances to be used in medicine may be ascertained and determined." This statement of aims was amplified by the President of the General Medical Council in his presidential address last November (*BRITISH MEDICAL JOURNAL*, SUPPLEMENT, 1925, vol. ii, p. 185), when he stated that "Any drug, in fact, which is (1) in current use over any considerable area, and (2) requires for the safety of the public that it should be exactly defined, in respect of source, preparation, standard of purity, etc., has a claim to admission."

The primary aim of the pharmacopoeia is, therefore, to fix standards for a certain selected number of drugs. There are several thousand drugs and preparations in use by the medical profession and scores of new compounds are introduced every year; hence it is impossible to fix official standards for every drug used in the treatment of disease throughout the British Empire, since this would need a library rather than a single volume. In point of fact, the present B.P. contains 400 drugs and 400 preparations, whilst the U.S.P. contains 650 drugs and preparations.

A comparison of either pharmacopoeia with the *British Pharmaceutical Codex*, or with Martindale and Westcott's *Extra Pharmacopoeia*, shows at once that the pharmacopoeias contain an account of only a small minority of the drugs used in medicine.

An examination of the pharmacopoeias of other countries proves that there is in practice a general practical agreement that a national pharmacopoeia can only include a selection of the drugs used in medicine. Stress has been laid on this necessity for selection because it is a point that is often ignored, and many arguments regarding the composition of the *British Pharmacopoeia* are based on the completely erroneous assumption that the volume ought to contain an account of all the drugs used in medicine.

Success in the production of a pharmacopoeia depends, therefore, first on a correct selection of the drugs to be included, and secondly on the provision of satisfactory standards for the drugs selected.

The Selection of Drugs.

The selection of drugs is a matter that concerns the medical profession rather than the pharmacists. This fact was recognized in the preparation of this new, tenth, revision of the *United States Pharmacopoeia* (U.S.P. X). The volume is the joint production of the medical profession,

the pharmacists, and the chemists, and the aim has been to prepare "a carefully selected list of medicinal substances of known origin" (p. xlii). The list of selections was drawn up by a subcommittee of sixteen physicians and five pharmacists, and was revised by a committee of twenty-one physicians (pp. ix and x). The choice of drugs was therefore left almost entirely to the physicians.

The principles of selection laid down by the President of the General Medical Council appear perfectly satisfactory, but of the two tests he has mentioned—namely, (a) frequency of use, and (b) necessity for standardization—the latter is obviously the more onerous. The pharmacopoeia is essentially a book of standards, and unless a drug has some action it is difficult to see upon what principle it can be standardized; the lack of a standard for such a drug could not involve any public danger.

It seems obvious that care should be taken to include all drugs with powerful actions which are in medical use, even though they may be used infrequently, and that there is less need for inclusion of such drugs as flavouring agents, carminatives, bitters, etc., since the accurate standardization of these latter is a matter of less importance to the public safety.

There is another factor of an economic nature which ought to be taken into consideration when compiling a pharmacopoeia, and this is that the provision of an official name and an official standard for a drug will often reduce the price of the drug.

Most new drugs are introduced to the medical profession under proprietary names, and it is desirable that the pharmacopoeia should include such drugs as soon as they become firmly established in medical practice. Very frequently such drugs are well known chemical compounds which are sold at a high price under a fancy name, and the medical profession can effect a considerable economy by prescribing these drugs under official names if such names are provided. For this same reason it is desirable that the pharmacopoeia should include as many drugs as possible which have distinctive and peculiar therapeutic actions, so that a medical practitioner, if he so desires, can confine the drugs he uses to pharmacopoeial preparations and thus avoid the expensive proprietary preparations. This last consideration will, of course, tend to swell the size of any pharmacopoeia, and therefore it is very important to avoid as far as possible the inclusion of useless or redundant drugs and preparations.

Any process of selection involves leaving out drugs which are in medical use. This is no great hardship, since the omission of a drug from the pharmacopoeia does not prevent any doctor from prescribing it if he so desires.

Any selection to be defensible must be based on general principles, and I suggest that the two chief principles should be—

(1) The inclusion of all powerful drugs in general use, on the ground that variation in the activity of such drugs is a public danger; and

(2) The inclusion of a sufficient number of drugs to ensure that any medical man wishing to prescribe a drug to produce a particular therapeutic effect should be able to find a drug of the type desired in the pharmacopoeia, and should thus be able to avoid the use of expensive proprietary articles.

In addition, a sufficient number of bases, flavouring agents, etc., must be included to permit the dispensing of standard preparations of uniform quality and appearance.

The selection of drugs should be based primarily on these principles, and after these requirements have been satisfied as many additional drugs can be added as may be considered desirable. This work of selection must be carried through by a committee considering the problem as a whole. For instance, there are between fifty and a hundred compounds which are used as hypnotics. No one would wish all these drugs admitted, but only a committee considering the needs of the pharmacopoeia as a whole can decide what number of hypnotics will form a proper proportion of the volume. Obviously a plebiscite cannot decide a matter of this nature; it can indicate which drugs are most popular, but cannot give any indication as to the number of any one class of drugs that ought to be admitted.

If a pharmacopoeia is to be judged by the proportion it

maintains between the various classes of drugs, and the number of important drugs for which it provides standards, then it must be admitted that the B.P. compares very unfavourably with the U.S.P.

The B.P. describes 400 separate drugs, but of these 40 are bases or colouring matters, 60 are flavouring agents, carminatives, and bitters, and 16 are simple astringents. About 50 more drugs are vegetable purgatives or anthelmintics. Any pharmacopoeia must, of course, contain an adequate representation of all the classes of drugs mentioned, but these numbers seem excessive. Moreover, of the remaining drugs there are a considerable number which have little or no known therapeutic action.

The U.S.P. in its last two revisions has made a determined effort to clear out rubbish, and it has, in this period, removed 432 drugs and preparations, and has added only 108. Thus it has reduced its scope to 650 drugs and preparations, most of which have a well defined therapeutic action. The process has consisted chiefly in deletion of galenicals of doubtful activity, and the insertion of new synthetic compounds. About 80 of the substances discarded, and 22 of the substances added, are in the present *British Pharmacopoeia*.

A more important difference between the two pharmacopoeias is that the U.S.P. contains a large number of potent drugs in general use which are not included in the *British Pharmacopoeia*. The following are a few of the more important drugs which are absent from the *British Pharmacopoeia*, but which appear in the U.S.P.

Class I. Drugs which were known before 1914.—Atophan, barium sulphate, emetine hydrochloride, pituitary extract, nitrous oxide, oxygen, novocain, salvarsan, antidiphtherial serum, antitetanic serum, theocine, small-pox vaccine, sodium veronal.

Class II. Drugs introduced to medicine since 1914.—Neosalvarsan, quinidine, sodium luminal, thyroxin.

The standardization of all these drugs is obviously desirable in the interests of public safety. In most cases the drugs have powerful therapeutic actions, and therefore any variation in their activity is a matter affecting the public safety. In the remaining cases, such as barium sulphate, nitrous oxide, and oxygen, the presence of impurities may be dangerous to life.

The *British Pharmacopoeia* is therefore overloaded with numbers of substances with little or no therapeutic activity, and does not include a considerable number of important drugs. In my opinion about 80 drugs might be deleted from the B.P. without causing the least public inconvenience. Of these 80 drugs only 10 are in the present edition of the U.S.P., and 40 have been deleted at the last two revisions of the U.S.P. On the other hand, there are at least 40 important drugs, nearly all of which are in the present U.S.P., which ought to be added to the B.P.

With regard to the selection of preparations it is very difficult to generalize, as a number of questions have to be considered. Certainly, however, it is undesirable to crowd the pharmacopoeia with a large number of preparations of the same substance. All of these preparations may be excellent, but since the pharmacopoeial space must be regarded as valuable a selection should be made of the most useful.

The U.S.P. has managed to eliminate redundant preparations more successfully than has the B.P. For example, the U.S.P. X contains only seven opium preparations, whereas the B.P. has no fewer than seventeen. Moreover, the U.S.P. saves much space by giving general instructions for the preparation of infusions, decoctions, and extracts.

The U.S.P. X is enabled to save space by the omission of widely used preparations of minor therapeutic importance, because most of these preparations are included in the National Formulary. This latter volume contains prescriptions for a large number of compounds in general use, and is recognized as a legal standard for drugs. Any scheme for the reform of our pharmacopoeia should include the official recognition of some volume of similar scope in this country.

In my opinion about 150 preparations might be deleted from the present B.P. Fewer than 10 of these are in U.S.P. X. Any such process of wholesale deletion would, of course, involve the removal of many drugs widely used by medical men; and, after all, the pharmacopoeia is not

"the Doctors' Bible," nor is it a textbook of therapeutics, but it is a list of official standards for those drugs for which standards are deemed necessary in the public interest. The omission of a drug from the pharmacopoeia does not prevent anyone from using it, but the inclusion of a drug is official recognition of the fact that it is considered sufficiently important to be in a selected list of drugs.

The Standardization of Drugs.

It is impossible to criticize the standards provided for drugs without considering the purposes for which the standards are provided. The standards in the U.S.P. X are legal standards, since the National Food and Drugs Act, 1906, and various State laws make the U.S.P. and the National Formulary the standards for drugs (U.S.P. X, p. x).

The standards of purity, etc., of the B.P. apparently are not intended for legal standards, since it is stated (p. xiv): "In short, the details of procedure in these and other chemical operations are now left to the skill and judgement of pharmacists and of analysts, who are assumed to be fully trained." No attempt, therefore, is made to make the standards foolproof or fraudproof, and in many cases an analytical chemist could, while keeping strictly within the limits of the directions provided, obtain very considerable variations. The *British Pharmacopoeia* is intended to instruct pharmacists how to prepare drugs for physicians. In practice it has been made a presumptive legal standard for other purposes, but it is unfair to blame the B.P. for being unsuited for purposes for which it was not intended.

On the other hand, the B.P. is bound to be the basis of important trade transactions. Drugs, when dispensed as medicines, must comply with the B.P. standards, and hence these standards are bound to form the basis of wholesale transactions. For this reason the standards of purity provided in the B.P. appear to need extensive revision and expansion. With regard to standards designed to measure therapeutic activity, however, there can be no doubt that it is most important that any which are provided by the B.P. should be adequate tests. The inclusion of useless drugs in a pharmacopoeia chiefly injures the reputation of the volume and does little direct harm, and although the omission of an important drug means a failure to provide any official safeguard as regards that drug, yet the provision of an inadequate standard is a far greater peril. It means the legalization of the sale of preparations of widely varying activity.

There are a number of important substances whose activity cannot at present be measured by chemical tests, and therefore require biological standardization. The editors of the U.S.P. recognized this fact in 1916, and laid down compulsory methods of biological assay for pituitary solution and for cannabis indica, and provided optional methods of biological assay for aconite, digitalis, strophanthus, squills, and suprarenal glands. The present U.S.P. has made biological assay compulsory for aconite, cannabis, digitalis, ergot, pituitary extract, strophanthus, and squills, and its regulations imply biological standardization for antitoxic serums, salvarsan, and neosalvarsan. It also provides an optional method of biological assay for the vitamin content of cod-liver oil.

The *British Pharmacopoeia* lays down no requirements regarding biological assay, and in consequence its standards legalize the sale of preparations of active and important drugs of the most widely varying potencies. For example, a tincture of digitalis might satisfy the B.P. requirements, and yet its activity might be anything from zero to more than normal strength.

The passing of the Therapeutic Substances Act, together with the action of the League of Nations in providing international standards for biological assay, will presumably ensure the inclusion of such assays in future editions of our pharmacopoeia. It is regrettable, however, that we should be more than ten years behind the *United States Pharmacopoeia* in adopting this method.

Mistakes in the B.P.

There are a certain number of actual mistakes in the B.P. which are avoided in the U.S.P. For example, the

hypodermic injection of cocaine is of 5 per cent. strength with a dose of 5 to 10 minims. This strength is far greater than necessary, and in consequence the dose is dangerously high.

Again, the methods laid down in the B.P. for the preparation of ergot extracts are such as to risk the loss of the whole of the alkaloids, which are the only active principles in ergot known to produce therapeutic effects when the drug is given by the mouth.

Naturally, the number of such errors is limited, and they can be avoided by simply copying the practice of other pharmacopoeias.

Nomenclature.

A comparison of the U.S.P. and the B.P. shows that the former is superior in nearly every respect, but although this comparison is very flattering to the U.S.P., yet it must not be supposed that this pharmacopoeia is above criticism. It still contains a number of obsolete drugs which might be deleted with advantage, and in the nomenclature chosen for new drugs the results seem in many instances to be rather unfortunate.

Most new drugs are introduced to the medical profession under proprietary names, and they are only adopted into the pharmacopoeia and given official names after they have become established as therapeutic agents, and after their proprietary names have got a firm hold. Obviously it is difficult to replace the general use of these proprietary names by official names, and it would be an obvious advantage were all pharmacopoeias to adopt a common official name. The U.S.P. X seems to have taken especial pains to avoid using any name that has been adopted by the B.P. For example, the chemical compound hexamethylenetetramine became widely known under the name urotropine, and was sold under this name and a dozen other fancy proprietary names for many years. The B.P. 1914 adopted the name hexamine, and the U.S.P. had previously adopted the name hexamethylenamine. Even this divergence was unfortunate, but now the U.S.P. X has rechristened the drug methenamine. Another example is diethyl barbituric acid, which is widely known as veronal. This drug was adopted by the B.P. as barbitone, and the drug has now been admitted to the U.S.P. X under the name barbital.

The only purpose of these official names is to try and replace the proprietary names, and there is no likelihood of this endeavour being successful unless all pharmacopoeias adopt the same name. Medical literature is international, and therefore international names are needed for drugs, and if the pharmacopoeial names are more local than the proprietary names the latter will persist. It is to be hoped that in future official names will be settled by international agreement.

The Editing of the Pharmacopoeias.

A comparison of the new edition of the U.S.P. with the current B.P. shows that the latter needs a very extensive revision if it is to be brought into line with modern medical practice. The difference between the two volumes cannot be accounted for entirely by the twelve years' interval between the dates of their appearance, because the contrast between the U.S.P. IX (1916) and the present B.P. (1914) is almost equally striking. A comparison of the mode of production of the two pharmacopoeias explains very largely the differences to be noted between them.

The U.S.P. was edited by an executive committee elected by a convention at which all interests affected by the pharmacopoeia were represented. The executive committee was divided into fifteen subcommittees which did the detailed work. These subcommittees were composed of experts of all kinds—clinicians, pharmacists, analytical chemists, pharmacologists, and so on. The task of selection of the drugs to be included was left practically entirely to the medical section of the executive committee, but the pharmacopoeia as a whole represents the joint production of the medical profession, the pharmacists, and the chemists.

The *British Pharmacopoeia*, on the other hand, is edited by a committee of members of the General Medical Council, and since the members of this Council are elected mainly to

fulfil the highly important duty of acting as a court of discipline in professional matters for the medical profession, it is only a chance if they happen to be particularly interested in the compilation of a pharmacopoeia.

In the past the editorial committee has been assisted by committees of reference in pharmacy and chemistry. The pharmacists have now declared that they are unwilling to co-operate on the past basis, for the reason that since they have to do a large proportion of the work they ought to have a voice in the editing of the pharmacopoeia.

The production of a satisfactory pharmacopoeia is a public need, and therefore it is to be hoped that some arrangement will be made that will ensure the co-operation of all the interests concerned.

The production of a new edition of the B.P. is so urgently needed that it will be necessary to produce a new volume as quickly as possible, and since most alterations in the pharmacopoeia involve a good deal of careful research work it will probably be necessary to rely in the next edition very largely on information provided by other pharmacopoeias. The expert knowledge available in England is, however, just as good as that in any other country, and it is offensive to national self-respect that we should be content with a parasitic existence, and should not endeavour to supply our quota of knowledge.

In the future some organization ought to be arranged that will ensure continuous research being carried out on pharmacopoeial problems, and a new edition ought to be brought out at least once every ten years. The U.S.P. appears regularly every ten years, and the last edition took five years to prepare. Careful consideration, however, is needed of the exact functions which a pharmacopoeia is intended to fulfil.

The defence of our present pharmacopoeia is that it is not intended as a guide in therapeutics, but that it registers the customs prevailing in the medical profession at the time of its production, and that the standards set forth are merely guides to the pharmacist to enable him to prepare uniform preparations of the type in popular demand by the medical profession. On these assumptions it would be possible to defend almost any pharmacopoeia, however bad. They are not justified in actual practice because it is admitted that a selection of drugs is exercised, and hence the appearance of a drug in the pharmacopoeia is a recognition of its importance.

The pharmacopoeia does not attempt to set limits to therapeutic practice, but it undoubtedly guides it to a certain extent. Under the present arrangement the practitioner knows that the pharmacopoeia is prepared by the leaders of the medical profession, and he does not realize that in selecting drugs they are not guided by their own opinion as to the value of drugs, but merely follow popular custom. Hence the appearance of a drug or preparation in the pharmacopoeia encourages its use, and as its retention is determined simply by the frequency with which it is used a vicious circle is established which checks the progress of therapeutics.

With regard to the standards formulated for drugs, the practitioner naturally believes that the standards for therapeutic efficiency are devised in accordance with the best scientific knowledge available, and does not realize that faulty standards have been defended simply on the ground that the preparations made according to these standards have been accepted by the profession without complaint.

In my opinion a pharmacopoeia ought to be compiled in accordance with the best medical opinion available, and the editors ought not to be afraid to take the responsibility of saying that the drugs included have been selected because they are believed to produce therapeutic actions, and that the preparations have been selected because they are believed to contain the active principles of the drugs in a stable and reliable form. At the same time there should be a clear definition of the purposes for which the standards laid down are suitable.

The assumption of such responsibility would, of course, be a departure from previous custom, but it would result in the production of a volume that would encourage rational therapeutics, and would not be merely a record of obsolescent medical customs.

England and Wales.

THE COST OF SANATORIUM TREATMENT.

THE Ministry of Health has issued a memorandum showing under various heads the weekly cost per patient at certain hospitals and sanatoriums in England and Wales for the treatment of tuberculosis. For comparison with the figures for the year ending March 31st, 1925, the corresponding figures for the previous two years have been inserted when available, so that it is possible to determine what economies have been made. In approximately half the institutions so compared a reduction of cost is evident, but in a nearly equal number there has been some increase. In many institutions additional expenditure has been necessary for renewals and repairs, though in some there has been a decline in the proportion of the beds actually occupied to the beds provided. When this is the case a relative increase in the cost of treatment is inevitable, and the Ministry reminds local authorities of the importance of keeping beds filled to the greatest possible extent. Another matter needing consideration is the numerical proportion of the institution staff to patients. The figures ranged from 2.3 per ten beds to 6, and even allowing for the fact that many of the institutions with the higher figures have the care of children as well as of adults, there would yet seem to be some room for improvement in this respect. The memorandum deserves careful study by those concerned in the administrative treatment of tuberculosis, since the wealth of detail contained in it will enable them to judge where improvement may possibly be effected in the institutions for which they are responsible.

STAFFORDSHIRE GENERAL INFIRMARY.

A new operating theatre was opened at the Staffordshire General Infirmary, on November 30th, 1925, by Sir John Bland-Sutton, Bt., President of the Royal College of Surgeons of England. The theatre, which cost £5,000 to erect, stands on the west side of the infirmary; it has a northern light, and includes a small theatre for septic cases, an anaesthetic room, a large operating theatre, with a surgeons' dressing room, a washing and a sterilizing room, and a preparation room. It is regarded as one of the most up-to-date and completely equipped operating theatres in the country. The Earl of Lichfield, president of the institution, gave an account of the way in which the money had been obtained, and referred to a generous legacy bequeathed earlier in the year. Sir John Bland-Sutton delivered an address on surgical operations past and present, and described the procedure in the pre-anaesthetic epoch. He showed how the discoveries of Pasteur and Lister had laid the foundations of modern surgery, and gave some amusing details of the earlier antiseptic methods. The present wonderful results in operative surgery were due largely to the rigorous precautions taken to avoid infection. Harmonious co-operation between a hospital board of management and the surgeons of the staff resulted in increased security for the patient, benefit to the community, and honour for the institution concerned. Dr. F. M. Blumer, senior honorary surgeon to the Infirmary, paid a cordial tribute to the great sympathy between the committee, the board of management, and the honorary staff during the forty years he had been connected with the Staffordshire General Infirmary.

WELSH HOSPITALS REUNION DINNER.

The Welsh hospitals reunion dinner, for all ranks, will be held at the Royal Hotel, Cardiff, on the evening of Saturday, January 16th. Colonel A. W. Sheen will preside. This is the day of the international rugby football match, England v. Wales, at Cardiff. A large attendance is expected at the dinner, and any who have not been communicated can obtain tickets and particulars from Staff-Sergeant R. W. Hedley, Waterworks Department, City Hall, Cardiff. The original Welsh Hospital was offered, and accepted by the War Office, for service in France about August 14th, 1914, but owing to war exigencies was established at Netley, where it remained throughout the war. No. 34 (the Welsh General Hospital) mobilized in April, 1916, and went to India, where it was established at

Deolali and enlarged to 3,000 beds. Most of the original Netley staff went with this hospital, the Netley Hospital being restaffed by Wales. Colonel A. W. Sheen commanded the Netley Hospital at first; on being appointed to command the oversea hospital he was succeeded by Lieut.-Colonel H. G. Cook. Both these hospitals did good work in the war, and throughout commanded the sympathy and support of the people of Wales.

Scotland.

SUCCESS IN PRACTICE.

FOLLOWING a practice which has obtained for several years past, the Edinburgh and Leith Division of the British Medical Association held a reception on Tuesday, December 15th, 1925, for those who were to graduate on December 18th. Dr. Keppie Paterson, chairman of the Edinburgh and Leith Division, occupied the chair, and a number of members of the Division were present. After tea and a musical programme, Professor G. M. Robertson delivered a short address. He said that his first duty was the obvious one of congratulating the graduands on having successfully passed all their professional examinations, and on their being about to place their feet on the first rung of the professional ladder. The first piece of advice he wished to give to those about to graduate was that they should without delay take the opportunity of being proposed as members of the British Medical Association, and for this he need only give two reasons. In the first place, there must be some body in a position to speak collectively in the name of the whole medical profession. Medical men had very properly subjected themselves to a self-denying ordinance which prevented them from advertising and from making themselves unduly prominent in the public eye. This was for the benefit of the public and of the profession, but it had the drawback that it made it less easy to give public expression to medical views; but this could be done by a large organization like the British Medical Association, which could express itself collectively. The second reason was totally different, and was of a personal nature. No man, although he had successfully passed all his professional examinations, should regard himself as knowing all within the domains of medicine. He must not cease to be a student after he had graduated, and to keep abreast of the times he must engage in post-graduate study and work at once. He ventured to say that there was no post-graduate teaching which approached nearly to the education they would receive by reading the weekly pages of the *BRITISH MEDICAL JOURNAL*. It was the finest post-graduate course in the world. Professor Robertson went on to say that from long experience he had found that it was not the clever and brilliant man who was usually most successful in practice. He thought that success came more to the man of character, the man upon whom his patients could rely, the man who attended to his patients, and who did the utmost that lay within his power, whatever that might be. Some men were phenomenally successful, and he believed that these men had not only been devoted to their patients, but that they had also had the benefit of luck. It was impossible to command this luck. Nevertheless, the speaker believed that it was the man who had both done his duty by his patients, and had the full benefit of good luck, who succeeded in this phenomenal way. Luck might also come to the man who had not attended to his patients as he ought to have done, but then this good luck did not benefit him in the same way and to the same extent. A man was sometimes unlucky, it might be, from a simple mistake. He remembered the case of a very distinguished Edinburgh physician who attended a patient with many complaints, and who attended her most carefully. On one occasion she had complained of sleeping badly, and he had prescribed a mild hypnotic. He had visited her a day or two afterwards and left without asking how the hypnotic had acted. This had appeared to her in her hypersensitive condition to be such evidence of gross neglect and incompetence that she gave him up as a doctor, and for years continued to abuse him in the most undeserved

way, simply for not inquiring as to her sleep at one visit. The graduands should never forget that they had to treat patients who were human beings, and not merely diseases; they must study human nature, and especially human weaknesses. He would not take advantage of this opportunity of saying how much attention should be given to the mental element in the complaints of patients, and in the remedies prescribed, because he had dealt with that subject in a recent promoter's address to graduands. He would conclude by wishing them success in the glorious profession which they had adopted, and also happiness in life. Apropos of this, he might say that a young man had recently come from the South of England to thank him for a piece of good advice which the speaker had given him at a most important juncture in his life. He had had the prospect of two appointments; one of these might have led to a very brilliant career, but the payment was relatively small, while the other appointment was not so good, but the salary was adequate, and as the young man was engaged he would be able to marry at once. The advice the speaker had given to him was that he should get married at once, because he believed that happiness was more desirable than a distinguished professional or scientific career, and he had quoted a poet who knew the secrets of the human heart:

"To make a happy fireside chime
To weans and wife,
Is the true pathos and sublime
Of human life."

EDINBURGH POST-GRADUATE COURSES.

The annual meeting of the lecturers taking part in the Edinburgh post-graduate courses was held on December 18th, 1925, in the Senate Hall of the University. Numerous suggestions were made regarding additions and improvements in the courses to be held during 1926. The numbers attending the courses held during July and August continue to increase year by year, and the secretary intimated that the number of entries received last summer during these months had been 150. Of those attending the courses, fifty-four had been graduates of Edinburgh University or possessed the diploma of the Scottish Conjoint Board, while the remainder included graduates from schools in America, Canada, Australia, New Zealand, India, China, and other schools of the United Kingdom. It was also reported that new features which had been added to the general medical course held last summer had included a series of lectures on dietetics, lecture demonstrations on insulin treatment, treatment by artificial pneumothorax, and sunlight treatment. The attendance at the general surgical course had showed a large increase, and, in this connexion, the question was discussed of providing additional post-graduate surgical clinics during the spring months. A series of medical clinics, which has been held for some years during the spring months twice weekly, will be resumed after the Christmas vacation. A suggestion was made that the course in diseases of children, which had hitherto been a separate course, combining medical and surgical treatment, should be incorporated with the general courses in medicine and surgery, so as to introduce into these a subject which is of great importance to the general practitioner. A handbook dealing with the arrangements for 1926 will be issued by the Post-Graduate Committee early in the coming year, and may be obtained on application to the Secretary, Post-Graduate Courses in Medicine, New University Buildings, Edinburgh.

CHANGES IN THE PUBLIC HEALTH SERVICES IN SCOTLAND.

The closing months of the year 1925 have witnessed several important changes in the public health services in Scotland. In Glasgow, Dr. A. K. Chalmers, who has filled the office of medical officer of health for many years with conspicuous ability and success, has retired, and Dr. A. S. M. Macgregor, O.B.E., D.P.H., receives the reward of good service as assistant by being promoted to the medical officership. In the county of Dumfries, similarly, Dr. John Ritchie, D.P.H., the deputy medical officer of health, has been promoted to succeed Dr. J. Maxwell Ross, who retires, after a long and honourable career, as medical officer of health for the county. Dr. Ritchie acts also

as principal school medical officer and medical officer of most of the smaller burghs in the county. In Perthshire a vacancy in the medical officership was caused by the death of Dr. John T. Graham, and the county council and the education authority have taken the opportunity to co-ordinate the two services by making a joint appointment. Dr. D. J. McLeish, D.P.H., who has been for a number of years school medical officer and tuberculosis officer for the county, has now received the joint appointment of county medical officer of health and school medical officer. He acts also as medical officer to some of the districts, but the burghs continue to appoint separate medical officers. In Aberdeenshire, where Dr. J. P. Watt, medical officer of health, has retired, almost complete co-ordination of the public health services in the county has been secured by a scheme the main objects of which are direction of the various branches of the public health services as a well ordered whole under one chief medical officer and the reviving of complete co-operation between the county public health staff and the general practitioners in the county. The chief medical officer will act as county medical officer and as district medical officer of health for the several districts of the county and as medical officer for all the burghs in the county except the burgh of Peterhead. Dr. Harry J. Rae, D.S.O., lately deputy medical officer of health and chief tuberculosis officer for the county, has been appointed chief medical officer of the co-ordinated medical services of the county of Aberdeen and burghs. The problem of the multiplicity of local authorities responsible for health affairs has long engaged the attention of all those interested in the advancement of public health in Scotland, and the merging of the smaller authorities has been recommended by a departmental committee. The experiment in voluntary co-ordination will be watched with sympathetic interest.

THE CARE OF CRIPPLES.

The publication of a leading article in our issue of December 12th, 1925, on the care and cure of crippled children has induced Dr. J. N. Meade, the chief medical officer under the Ayrshire Education Authority, to send us a copy of his annual report for the year ending last July. We gather from information that has been published from time to time that the educational authorities in Scotland are a little behindhand in their provision for the treatment of physically defective children, but Dr. Meade's report shows that in Ayrshire a substantial foundation is being laid, although it is still necessary to send cases to Glasgow for operations, and one child appears to be provided with orthopaedic treatment at the cost of the Ayrshire authority as far away as St. Vincent's Orthopaedic Hospital at Pinner, Middlesex. We learn that St. Leonard's Home, Ayr, has been acquired for the purposes of a special school for defective children; 16 are in residence and 38 attend daily, being conveyed to school in a motor ambulance carriage, making in all 54 physically defective children. Provision for the residence of physically defective children is an unusual feature in special schools, and is probably made necessary by difficulties of transport. We are glad to note that advantage is taken of this circumstance to treat the disabilities of children. In May last Mr. Norman Davidson, O.B.E., F.R.C.S., was appointed orthopaedic surgeon to the home, and has since made regular visits, prescribing treatment by appliances and taking cases requiring operation into the Victoria Infirmary, Glasgow. As Dr. Meade says: "The problem of the cripple child deserves more serious consideration than it has hitherto received, and now that at least the nucleus of an orthopaedic centre has been formed, it is hoped that its development will bring amelioration to many helpless children in the area." Elsewhere in this report it is recorded that in various places in Ayrshire there are in existence, or in course of formation, special schools or special classes for mentally defective children. It seems possible that in the future out of these may be developed orthopaedic clinics, and that perhaps St. Leonard's Home might develop into a central orthopaedic hospital. But judging from the records of medical examinations of school children, the number of cripples in Ayrshire is not very great, and a scheme linking

up several counties might prove to be the most promising, if the Oxford, Bucks, and Berks system were adopted as a model. We congratulate the Ayrshire Education Authority on its enterprise, and hope that this may be only an earnest of what is to come in the care and cure of crippled children in Scotland.

Ireland.

CENTENARY OF THE NEW MEDICAL SCHOOL, TRINITY COLLEGE, DUBLIN.

THE centenary of the opening of what is still called the New Medical School, Trinity College, Dublin, is about to be celebrated. The building, which was commenced in 1823, was formally opened on November 1st, 1825, by Professor James Macartney, university professor of anatomy and chirurgery. The centenary ceremony will take place on Wednesday, January 13th, when Dr. T. P. C. Kirkpatrick, Litt.D., will deliver an address on the early history of the school of physic, at a meeting to be held in the school, presided over by the Provost. All medical graduates of the university are invited to be present. On the same evening a dinner will be held in the dining hall of the college at £4.5s, for which medical graduates may obtain tickets at £1 1s. each. Academic dress will be worn. As accommodation is limited, applications for dinner tickets should be made at as early a date as possible to the Dean of the Faculty of Physic, Trinity College, Dublin.

MEMORIAL TO DR. J. C. MARTIN OF PORTRUSH.

A life-size portrait in oils of the late Dr. J. C. Martin was unveiled on December 22nd, 1925, at the Hopefield Cottage Hospital, Portrush. By the side of the portrait is a brass tablet mounted on oak bearing the following inscription:

"This painting has been placed here by public subscription in loving remembrance of J. C. Martin, Esq., M.D., J.P., who died January 31st, 1925. A skilful physician and surgeon and a very courteous gentleman, his death was deplored by all who knew him, but particularly by the patients and staff of Hopefield Cottage Hospital, with the founding and work of which he was closely connected."

Correspondence.

TREATMENT OF CARBON MONOXIDE POISONING.

SIR,—I am glad to find, from their letters in the *BRITISH MEDICAL JOURNAL* of December 19th, 1925 (p. 1199), that both Sir Charles Gordon-Watson and Mr. Douglas Kerr are in agreement with me in their interpretation of the striking cases in which the former transfused blood successfully. At the end of his letter, however, Sir Charles puts the very pertinent question as to what can be done by a medical man faced with a patient who has been rendered unconscious by carbon monoxide poisoning, for instance, in a garage.

If everything requisite were available the most effective and quickest method of treatment would be, I think (apart from artificial respiration if the breathing had stopped), the administration through a mask of oxygen mixed with about 5 per cent. carbon dioxide, as recommended by Henderson. The advantage of the oxygen is, first, that it immediately adds to the blood a supplementary supply of oxygen in simple physical solution, and secondly, that thereafter it drives out CO far faster than if the same amount of air were breathed. But, as Henderson and Haggard have shown, the blood and whole body have lost so much CO₂ during the excessive breathing of acute CO poisoning that as soon as the want of oxygen is partially relieved by the oxygen a condition bordering on apnoea is produced, so that as a matter of fact the CO is only driven out slowly unless CO₂ is added to the oxygen in order to stimulate breathing. With this addition the breathing is so increased that the CO is driven out very rapidly; and by no other means can the want of oxygen in CO poisoning be relieved so rapidly.

In a recent paper on CO poisoning in mines (*Trans. Inst. of Mining Engineers*, lxxviii, p. 271) I drew attention to the fact that with a given saturation of the blood with CO the symptoms are much more severe when an animal is breathing pure air than when it is breathing expired air or air to which the same proportion of CO₂ has been added as in expired air. This is certainly due to the fact that the circulation is more rapid, and hence the supply of oxygen to the brain less restricted, when excessive loss of CO₂ by the blood in the lungs is prevented. We are thus furnished with a probable explanation of why men working at underground fires in air vitiated by both CO₂ and CO often fall unconscious on returning to pure air. The old-fashioned remedy, still sometimes used, of digging a turf and laying a gassed man with his face in the hole, may also have its explanation in the beneficial action of rebreathing his own CO₂. An apparatus which simply furnishes to the patient a mixture of about 4 or 5 per cent. of CO₂ (for instance, the "Carbethea" apparatus designed for this purpose by Messrs. Siebe Gorman and Co. on my suggestion) is very effective in treating CO poisoning, and has advantages on the score of lightness and lasting power, though the oxygen and CO₂ mixture is superior where weight does not matter.

In very many cases of CO poisoning no apparatus whatever will be available until too late for much, or perhaps any, benefit to be obtained from it. From the results of the animal experiments I am convinced, however, that good results could be obtained by means of some simple arrangement for making the patient inhale as much as possible of the expired air of another person. For instance, the donor might expire through a tube made from a rolled-up pamphlet, the lower end of this tube being held close to the patient's mouth or nose, and surrounded with a woollen scarf or similar material to hinder lateral escape of the expired air. If the expirations of the donor were synchronized with the inspirations of the patient the latter would receive fresh expired air, more or less free from CO, at each inspiration. Such treatment, unorthodox as it may at first sight appear, definitely aims at producing some immediate relief by quickening the circulation, and at hastening the elimination of CO by increasing the volume of air breathed.—I am, etc.,

J. S. HALDANE.

Oxford, Dec. 21st, 1925.

THE ULTIMATE FATE OF PATIENTS WHO RECOVER FROM AN ATTACK OF INSANITY.

SIR,—Is it not the case that our knowledge of the fate of patients discharged well from the various kinds of institution for care and treatment of mental disorder is very inadequate? The annual reports issued by these, which the urging of conscience, or of pitiless obsession, compels me to peruse, do not deal with the matter. It would be interesting to learn the experience of public mental hospitals, registered hospitals for the insane, and licensed houses ("Board of Control," "licensed house"—these and like delectable expressions have been commended to the attention of the prohibitionists, who, we trust, are represented on the Royal Commission now inquiring into the subject of the lunacy laws) on the matters of the duration of the period of good health on recovery and frequency of relapse. One would think the best statistics would come from the rate-supported mental hospitals, for the obvious reasons that the rate-aided in a given area, who had been treated in the hospital for that area, are, for the most part, permanent residents therein, and would, on relapse, be taken to the same hospital in the great majority of cases. Should such have removed while well to another area they would, in perhaps the majority of instances, still have a settlement in the original area, and would, consequently, if admitted to the hospital of the other area, be transferred to that of the original one.

But, in my opinion, as one who has worked long years in public mental hospitals, and had regular reports for some years from an after-care association regarding discharged patients and their homes and circumstances, and who has also cognizance from the depressing experience of an out-patient clinic in psychiatry (where patients discharged from a public mental hospital are regularly seen)

of the powerful factors which militate against the maintenance of health by the convalescent poor, if our inquiry is limited to the rate-aided, we shall obtain results calculated unduly to discourage us. With this class, the work done at the hospital is often rapidly undone on the patient's discharge; the efforts of the hospital, in fact, are not backed up outside. We are entitled to expect that retention of health on the part of the recovered patient would be of longer duration, relapse less frequent, amongst the better educated, better-to-do classes. For obvious reasons, let me mention two only: a long period of rest and change is possible on convalescence, with periodic, sufficient holidays; adoption of precautionary measures (as advised) promptly, on recognition of symptoms of ill health, is more likely. It is possible that registered hospitals and licensed houses could also supply the desired statistics in respect of the voluntary boarder class which they are allowed to receive.

To obtain information of value it would seem that institutions of the above classes would require to have as accurate a record as possible of the subsequent history of the cases discharged recovered for a total period up to, say, twenty years, dealing with cases discharged during the first fifteen years. What was the duration of the period of good health, what the relapse percentage, what the frequency of relapse, in relapsing cases, what the percentage of those who did not relapse?

I am aware that the subject of relapse of insanity is touched upon in the article entitled "Statistics of insanity," by Dr. Hack Tuke, in his *Dictionary of Psychological Medicine*. Dr. Tuke conjectured that only 27 per cent. "of the total persons admitted" are likely to die sane. He also makes the statement, based upon statistics of the York Retreat (a registered hospital for the insane), got out by Dr. Thurnan, that of eleven persons attacked by insanity six recovered and five died sooner or later during the attack. Of the six, not more than two remained well during the rest of their lives, the other four sustained subsequent attacks, during which three of them died. It is possible that more recent and fuller information is available bearing upon the subject of this letter. The textbooks which I have, British and foreign, do not deal with it. Kraepelin, whose textbook I do not at present possess, may do so. But I doubt very much whether any comparative information in respect of different social classes of the community exists.—I am, etc.,

EDWIN GOODALL.

Cardiff City Mental Hospital,
Dec. 28th, 1925.

TABES DORSALIS IN SURGICAL PRACTICE.

SIR,—Mr. Watson Jones's memorandum on this subject is apposite (December 26th, 1925, p. 1224). No common disease is missed more frequently than tabes dorsalis, and yet it is as a rule easy to diagnose. Guy's men know the story attributed to a former surgeon. When called to an abdominal emergency he murmured repeatedly "Gums and jerks." But tabes dorsalis can be diagnosed prior to the stage of abolition of tendon jerks and in some cases of long standing the tendon jerks remain. Moreover, there is nothing impossible in a correct diagnosis in a patient whose eyes are glass and whose legs are wood.

A man now under my care was admitted to a surgical ward with a provisional diagnosis of nerve involvement in the scar of a long-distant amputation through the hip-joint. He had well marked tabes dorsalis, and the pains about the scar were merely part of the pains of the disease, which had existed for many years in his phantom limb—a remarkable case. His knee-jerk is brisk, his ankle-jerk abolished. His tests, then and since, are all negative as regards syphilis, but his syphilis has never been treated. We meet so many cases of tabes dorsalis, a disease of syphilis, in which, either by the lapse of time or as a result of treatment, there is no longer any serological evidence of syphilis, that it is erroneous to speak of "confirming" the diagnosis of tabes dorsalis by examination of the cerebro-spinal fluid. A positive fluid may assist in the diagnosis of a difficult case. A negative fluid should never invalidate a clinical diagnosis.

I have seen four cases of tabes dorsalis in which haemat-

emesis occurred as a symptom. Three of these had already been submitted to laparotomy. The fourth case is under my care at the moment, a thin woman of 60 who eight weeks ago had a first haematemesis without other gastric disability save long-standing moderate dyspepsia. She had been thought to have pulmonary tuberculosis with haemoptysis. She has numerous and striking signs of tabes dorsalis. Her knee-jerks are active, her ankle-jerks abolished. Her tests for syphilis are all negative.

Mr. Watson Jones's note strengthens me in the opinion which I hold strongly, and which I teach whenever I can, that except in cases of trauma no laparotomy should be performed save with the sanction of the physician, unless, of course, the surgeon is at heart "a physician doomed to the practice of surgery." This opinion is based on a varied personal experience of abdominal manifestations in tabes dorsalis, and also on a personal experience of six cases of long-standing hysterical regurgitation of gastric contents, in all of which needless laparotomy had previously been performed, and in one of them, now under observation, four times.—I am, etc.,

HILDRED CARLILL, M.D. Cantab.,
Physician to Westminster Hospital.

London, W.I, Dec. 25th, 1925.

TREPANING AND TREPHINING.

SIR,—The crown-shaped saw now usually called a trephine is very ancient. One was found in the ruins of Nineveh, though there seem to be no extant Greek or Roman samples. Hippocrates (*Wounds in the Head*) calls it simply a saw (*πίπων*), but distinguishes it clearly from the drill (*τρύπανον*). Its later names were *χουρεϊς* and *χουρικιον* in Greek and *modiolus* in Latin, under which name Celsus describes it. It had no cross-handle, and was worked by bow and cord like a drill. But, since it is a saw and not a drill, no misuse seems to justify the application of the word for drill to both instruments. Woodall gave it a handle and invented the name "trephine" from *tres fines*! It is a convenient term for distinguishing the two, and perhaps the simplest way of translating the Greek and Latin titles where "trepan" is obviously inadmissible. But there are objections to the word, and perhaps some reader will suggest something better for the new edition of "Liddell and Scott."—I am, etc.,

Oxford, Dec. 25th, 1925.

EDWARD T. WITHINGTON.

SIR,—Dr. Clowes's valuable letter in the *JOURNAL* of December 26th, 1925 (p. 1247), on the terms "trepanning" and "trephining" is interesting from both an historical and etymological aspect. Concerning the instruments employed, we know that trepanning (the making of a hole in a skull with a metal borer) and trephining (making a hole with a circular saw) both stand for a similar operation, the former method having been superseded by the latter for practical purposes.

Dr. Clowes states: "If a generic term is required I think it should be 'trepanning,' which might logically include both the modern and the prehistoric operation, and that it should always be applied to the latter." It must be remembered that by far the larger number of Neolithic trephinations in Western Europe, during a period ending about 2000 B.C., were not done by boring implements. The scraping method was by far the commoner one employed, and specimens discovered exhibiting flint-boring openings in the skull have been comparatively few. One is, therefore, not logically justified in saying that the word "trepanning" would embrace the Neolithic European procedure of opening the skull. No name has hitherto been given to this method.

Broadly speaking, the modern word "trephination" implies the making of an opening into the cranial cavity. This opening may be begun by circular-sawing and enlarged by the saw, the chisel, or the gouge. As the British have *trephined*, his word, let us not go back to mediaeval times *trepanned*, unless that precedent can be logically proved to be better than the one we now employ; and Dr. Clowes has himself pointed out that the word "trephining" is the one that is used by experts, while the word "trepanning" continues to be used almost exclusively by lay writers. The only argument on the other side appears

to be of an international character, in that the French have only one word, regardless of all etymology, for this operation, whether it be Neolithic, mediæval, or modern, and that is *trépanation*.—I am, etc.,

London, N.S., Dec. 26th, 1925.

T. WILSON PARRY.

PREVENTION OF THE COMMON COLD.

SIR,—I am quite convinced that Dr. F. R. Walters (BRITISH MEDICAL JOURNAL, November 21st, 1925, p. 980) is quite right that dust, naturally carrying germs of many kinds, is very frequently the cause of "common colds."

The old method of "dusting" by a feather duster simply changes the place of the dust and does not get rid of it. It fills the air of the room with the dust and is unavoidably inhaled.

I do not know how common the use of "vacuum cleaners" is in Great Britain. In the United States they are very widely used, one might almost say becoming universal. The dust is sucked up into a bag and disposed of by burning or otherwise. Small objects are also sucked up unless too heavy.—I am, etc.,

Philadelphia, Dec. 6th, 1925.

W. W. KEEN.

NASAL DOUCHING.

SIR,—I have recently seen in the lay press a wholesome and wholesale attack on the prevalent habit of nasal douching—whether by sniffing the solution (usually salt and water) through the nostrils or with the help of a glass douche. It was stated that great danger attended this practice—in particular, middle-ear trouble and deafness.

For many years I have advised some of my patients to douche the nostrils with saline, the result being that within the past couple of weeks I have been asked by some of these patients whether they should not discontinue the practice because they read in the paper that it was condemned by a "Harley Street doctor."

I wonder how many of us really consider that nasal douching generally is dangerous. If douching is done by sniffing the solution from a container or from the hands, the suction action is carried out by the lungs, and as soon as the solution enters the nasopharynx it is carried down by this suction as well as by gravity. There cannot therefore be any rise of pressure in the naso-pharyngeal space which might force the solution into the Eustachian tubes.

The usual method of douching (as carried out by a doctor), in which the solution is forced up the more obstructed nostril and allowed to come out through the other nostril, does not seem to be a safer method, as the patient is asked to breathe through the mouth in order to cut off the naso-pharyngeal space, and unless the nostril which carries the return flow is quite free from obstruction there might possibly be a rise of pressure affecting the Eustachian tube. Again, in this latter method, is not the solution more likely to be forced into one of the nasal accessory sinuses, seeing that it is being syringed through a more or less obstructed nostril, than in the "sniffing" method where the two nostrils are in action or possible action and the patient is not breathing through the mouth and the naso-pharyngeal space is not therefore cut off by the soft palate?

Patients, while free from any apparent nasal trouble, such as enlarged turbinates, polypi, etc., are often prone to a "cold in the head," which is a frequent precursor of severe influenza. In this type of case nasal douching might well be looked upon as a preventive of influenza, and think it is.

Are we going to tell our patients that nasal douching is dangerous?—I am, etc.,

EDWARD P. COYNE, M.B., B.Ch.

Neath, Glamorgan, Dec. 10th, 1925.

"NEO-CARDIOLOGY."

SIR,—Dr. G. Arbour Stephens (December 26th, 1925, 1245) attributes to me the statement that "it is quite impossible to learn anything by clinical examination of the condition of the myocardium." Such alleged statement "most emphatically" repudiate.

Your readers have cause for gratitude to "A General Physician" for his thoughtful and convincing letter, a

timely emollient at the Christmas season to what threatened to become an acrimonious correspondence. With all that he writes I am in full accord, and with these remarks my contribution to the discussion ends.—I am, etc.,

Hove, Dec. 27th, 1925.

DONALD HALL.

Obituary.

JAMES RITCHIE, M.D., F.R.C.P.ED., F.R.C.S.ED.,
Edinburgh.

DR. JAMES RITCHIE, who had been for many years a well known medical practitioner in Edinburgh, died after a short illness at his residence in Slateford, near Edinburgh, on December 10th, 1925. Although he was in his 85th year and had retired from practice some years ago he still enjoyed a great measure of bodily and mental vigour, and maintained an active interest in many branches of public work. He took the diploma of M.R.C.S.Eng. in 1872, and graduated in medicine, with honours, at the University of Edinburgh in the same year; in 1891 he proceeded to the degree of M.D., receiving a gold medal for his thesis. In 1874 he became F.R.C.S.ED., and in 1882 took the M.R.C.P.ED., proceeding to the Fellowship in the following year. After graduation, he acted for six months as house-surgeon to the late Professor Annandale, and in the following summer was resident physician to Sir Thomas Grainger Stewart. Among his fellow residents were Dr. Alexander James, Dr. C. W. MacGillivray, and Sir George Beatson. For a short time he acted as assistant to Sir Thomas Grainger Stewart in the chair of practice of medicine at the university, but his time very soon became fully occupied by the claims of a large general practice, which he continued to enjoy until he retired.

Despite the claims of practice he found time to write occasional papers, such as an article on general cystic degeneration of the adult kidney, published in the *Reports* of the laboratory of the Royal College of Physicians, Edinburgh, in 1892; on osteomalacia, published in the *Transactions* of the Obstetrical Society of Edinburgh in 1895; and on general secondary carcinoma of the bones, published in the *Transactions* of the Medico-Chirurgical Society of Edinburgh in 1896. He gave special attention to obstetrics and was an examiner in this subject for the Royal College of Surgeons of Edinburgh; he served a term of office as president, both of the Edinburgh Obstetrical Society and of the Edinburgh Medico-Chirurgical Society. He took an active interest in the affairs of the British Medical Association. Before the establishment of Divisions he was for several years a member of the Parliamentary Bills Committee. From 1899 to 1915 he was honorary treasurer of the Edinburgh Branch, and became its president in 1917. In 1904 he was chairman of the North-West Edinburgh Division, and in 1911 was elected the first chairman of the Edinburgh and Leith Division, formed by the amalgamation of three previously existing Divisions in the city; he held this office during the important period when negotiations were in progress respecting the National Health Insurance Act. Dr. Ritchie also took a very prominent position in work connected with the United Free Church of Scotland, and was for some years president of the Edinburgh Medical Missionary Society. He was a man of modest and unassuming character, and in a very high degree was respected and beloved by his large circle of patients and friends. His wife died twenty-five years ago; he is survived by two sons, who are both medical practitioners, and by four daughters.

DAVID LLOYD OWEN, M.D., F.R.C.S.I.,

Consulting Ophthalmic Surgeon, Birmingham General Hospital.

THE death occurred suddenly on Christmas evening, at Harlech, North Wales, of Dr. David Lloyd Owen, formerly a well known ophthalmologist in Birmingham. He was consulting surgeon to the Birmingham and Midland Eye Hospital, and consulting ophthalmic surgeon both to the Birmingham General Hospital and the Hospital for Sick

Owen was born in 1843, the son of

the Rev. D. Owen, originally of Darowen, Montgomeryshire, and was educated in Birmingham and later in Paris. He took the diploma of M.R.C.S.Eng. in 1865, and became F.R.C.S.I. in 1880. Subsequently he graduated M.B., B.Ch.Birm. in 1901, and proceeded M.D. in the following year. He resided for a considerable period in Edgbaston, afterwards at Newhall Street, and later at Four Oaks, where he remained until his retirement five years ago.

Dr. Lloyd Owen was an ex-president of the Midland Medical Society, a former vice-president of the Birmingham Medical Institute and of the Ophthalmological Society, and an ex-president of the Birmingham Branch of the British Medical Association. He served as president of the Section of Ophthalmology at the Association held its Annual Meeting in 1890. He was the author of a number of papers on the eye, and in 1890 published a manual, *The Elements of Ophthalmic Therapeutics*. In 1896 he delivered the Middlemore Lecture, taking as his subject "Pain in eye disease, its character and its relief."

He was a justice of the peace for the county of Warwick and the borough of Sutton Coldfield. On leaving Birmingham he was presented by Undeb y Brythoniaid (the Birmingham Welsh Society), of which he was founder, with a replica of the presidential badge of the Undeb. Outside his professional work his chief interests were Freemasonry, archaeology, and genealogy.

SAMUEL FLEMING, M.B., O.M., Metropolitan Police Magistrate.

MR. SAMUEL FLEMING, metropolitan police magistrate of Lambeth, died on December 20th, 1925, on board the steamer *Armada Castle*, on his way to the Cape. He was born on May 24th, 1865, the son of Mr. Frederick Grant Fleming, and was educated at University College, London, and Edinburgh University, where he graduated M.B., O.M. in 1890; he took the D.P.H. at Cambridge in 1893. Leaving the medical profession for the law, he was called to the Bar by Gray's Inn and the Middle Temple in 1897, and joined the North-Eastern Circuit, practising at the Durham, Leeds, Sheffield, Bradford, and Rotherham sessions. During the war he was legal adviser and judge advocate of the Aldershot Command, afterwards legal adviser to the Army Medical Department, and received a brevet lieutenant-colonelcy in the R.A.M.O. in 1918, having become major in 1916. In 1920 he was appointed Recorder of Doncaster, but resigned that post in the following year, when he was appointed a metropolitan police magistrate. He sat at first at Greenwich and Woolwich, and was transferred to Lambeth in 1924. He had been elected a member of the Bar Council in 1920. In 1892 he married Elizabeth, daughter of the late Colonel W. C. Ball, C.B., and at the time of his death was on his way, with his wife, to visit one of his daughters, who is married to Major Pict Vanderbyl.

Mr. Fleming was, we believe, the first and only medical man who has filled the post of metropolitan police magistrate. In this connexion we may remark that the present generation has seen the creation of the first medical peers, Lord Lister (1897), Lord Ilkeston (1910), Lord Finlay (1916), and Lord Dawson of Penn (1920); the first medical Lord Chancellor, Viscount Finlay (1916-18); the first medical ambassador, Sir Auckland Geddes (1920-24); the first medical Lord Mayor of London, Sir Thomas Crosby (1911); and the first medical Poet Laureate, Dr. Robert Bridges (1913).

The death of Dr. ALFRED BOWLES took place suddenly from heart failure at his residence at Eastbourne on December 21st, 1925, in his eighty-fourth year. He was active in his professional work to the end. This consisted almost entirely in the care of mental patients in his own house, and he had a large experience in this branch of medicine, for which he was particularly well suited by his tact and kindly disposition. His name was familiar to most of the London psychiatrists and neurologists of the present and past generations, and he was well known to the medical men in Sussex, who frequently sought his

expert advice. He was a member of the British Medical and Royal Medico-Psychological Associations and of the Eastbourne Medical Association. Dr. Bowles was educated at University College and St. Mary's Hospital, and took the diplomas of M.R.C.S. and L.R.C.P. in 1899. For some years he was assistant medical officer at Moorcroft, Dr. Stilwell's establishment at Hillingdon, Uxbridge. Dr. Bowles leaves a widow and a son to mourn his loss, and a wide circle of friends.

The Services.

TERRITORIAL ARMY MEDICAL OFFICERS' ASSOCIATION.

A DINNER for Territorial medical officers, active and retired, will be held at the Café Royal, Regent Street, London, on Friday, February 12th, at 8 p.m. Officers intending to be present are asked to communicate without delay with Colonel M. B. Ray, D.S.O., M.D., A.D.M.S., honorary secretary, at the offices of the Territorial Army Medical Officers' Association, 37, Russell Square, London, W.C.1. Lieut.-General Sir Hugh S. Jevons, K.C.B., K.B.E., Director-General of the Territorial Army, and Lieut.-General Sir William B. Leishman, K.C.B., K.C.M.G., F.R.S., Director-General of the Army Medical Services, have intimated their intention to be present.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Board of the Faculty of Medicine.

THE Board of the Faculty of Medicine has co-opted E. Farguhar Buzzard, D.M., Magdalen College, and Malcolm H. MacKeith, D.M., Fellow of Magdalen College, as members of the Board for two years from the first day of Hilary term, 1926.

Francis Gotch Memorial Prize in Physiology, 1925.

The board of management of the Francis Gotch Memorial Fund has reported to the Vice-Chancellor that, as a result of the examination of candidates held on December 1st, 1925, it has awarded the medal and the prize of £5 to Joyce Wright, B.A., Somerville College; *proxime accessit*, Jack William Pugh, B.A., University College.

UNIVERSITY OF CAMBRIDGE.

THE following candidates have been approved at the examination indicated:

THIRD M.B., B.CHIR.—Part I. *Surgery, Midwifery, and Gynaecology*:
A. R. Adderley, D. Ascrman, G. W. Bamber, J. O. W. Bland, G. C. W. Brown, J. A. S. Brown, P. R. Buckton, G. P. Chandler, P. F. Chandler, H. A. Clegg, L. C. Cook, W. F. Cooper, B. Cunningham, T. S. Dwyer, H. V. Dicks, J. Dockray, O. D. Donaldson, A. B. Eddowes, J. B. Ellison, A. W. Ewing, T. D. W. Frost, S. J. P. Gray, J. C. P. Grey, W. S. Grove, H. J. Heathcote, J. D. Hindley-Smith, G. G. H.

A. Simpson Smith, H. B. Stallard, E. J. E. Topham, E. A. Trim, J. L. Warner, H. M. Woodman.

* Allowed to take Surgery only by Grace 61 of November 14th, 1925.

UNIVERSITY OF BIRMINGHAM.

AT a congregation held on December 18th, 1925, the following medical degrees were conferred:

M.D. Constance R. La Trobe
M.B.

SOCIETY OF APOTHECARIES OF LONDON:

THE following candidates have passed in the subjects indicated:

SURGERY: B. A. Perott, C. E. Hagenbach, B. D. Jais, M. F. Whitby, J. Shilko.
M.E. For M.M.

* Section II.

The diploma of the Society has been granted to Messrs. R. F. Ashkeny, S. Douglas, C. E. Hagenbach, T. A. Lazaro, M. Schwartzman, and F. Smith.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Acts of medical interest passed by Parliament during the session just concluded, with their dates of coming into force, are:

- Therapeutic Substances Act (to be fixed by Order in Council between August 7th, 1926, and August 7th, 1927).
- Workmen's Compensation Act (May 1st, 1926).
- Government of India (Civil Services) Act (December 22nd, 1925).
- Mental Deficiency (Amendment) Act (July 31st, 1925).
- Public Health Act: Unification (August 7th, 1925).
- Dangerous Drugs Act (to be fixed by Order in Council).
- Public Health (Scotland) Amendment Act (December 10th, 1925).

Diphtheria and Scarlet Fever: Errors in Diagnosis.—In answer to Mr. Bromfield, the Minister of Health stated that he was aware that 31.5 per cent. of the cases notified as diphtheria, and 13.6 per cent. of the cases notified as scarlet fever, and sent to the infectious diseases hospitals of the Metropolitan Asylums Board in the year 1924, were found after admission to be suffering from something else or from no disease at all. He was informed that the increase in the number of cases of diphtheria admitted during 1924 to the infectious diseases hospitals of the Metropolitan Asylums Board in which the diagnosis had to be revised might be accounted for by the increasing recognition on the part of medical practitioners of the necessity, in the interests of the patient, of immediate removal to hospital for the purpose of securing treatment as early as possible without waiting for the receipt of a laboratory report. No figures were available to show whether the percentages notified in error were as high or higher throughout the country. In cases in which the diagnosis made at the Metropolitan Asylums Board's hospitals was not in agreement with that of the notifying practitioner, the information was communicated to the medical officer of health of the sanitary district from which the patient was removed, in order to ensure the accuracy of his statistics. Information as to the diagnosis made at the hospital was given to the parents on request. No information was available as to the number, if any, of these cases which contracted scarlet fever or diphtheria after admission to hospital. He was advised that there was no statutory provision under which a medical practitioner could be called upon to refund the fee for a notification certificate in a case in which his diagnosis was not in agreement with that subsequently made at the hospital, and it would, in his opinion, be undesirable in the public interest that such a course should be adopted.

Bottles for Poisonous Preparations.—The Minister of Health announces that regulations under the Poisons and Pharmacy Acts require that preparations containing scheduled poisons intended for external application should be supplied in bottles distinguishable by touch. The question of the extension of these regulations to other preparations containing scheduled poisons was a matter for the Privy Council, and he would bring to the notice of the Lord President the suggestion lately made by a coroner's jury at Camberwell that all poisons should be sold in blue ribbed bottles instead of in white.

Encephalitis Lethargica.—Sir Kingsley Wood, in a written reply to Captain Fairfax, said that 1,157 deaths had been provisionally attributed to encephalitis lethargica in England and Wales during 1925 down to the end of October. The Ministry of Health had issued reports and memoranda in recent years in which the principal facts ascertained regarding the occurrence of this disease and the manner of its spread had been set out. Efforts were being made in conjunction with the Medical Research Council to add to knowledge of the causes of this disease and the possibilities of avoiding it.

Medical News.

THE Joint Nursing and Midwives' Council of Northern Ireland, being about to revise its list of examiners, invites applications from registered medical practitioners, including women, who would be willing to act. Particulars can be obtained from the Registrar, 118, Great Victoria Street, Belfast, to whom applications should be sent not later than January 15th.

THE Council of the Royal Institute of Public Health has awarded the Harben gold medal for 1925 (of the value of fifty guineas) to Professor Baron Shibusaburo Kitasato, M.D., Director of the Royal Japanese Institute for Infectious Diseases, for his "eminent services to the public health." The Smith award (a bronze statuette of Hygieia by Charles L. Hartwell, R.A.) has been made to Professor Matthew Hay, M.D., LL.D., F.R.C.P.I., for his "outstanding merit as a medical officer of health."

THE National Association for the Prevention of Infant Mortality and for the Welfare of Infancy (117, Piccadilly, W.1) announces that a course of lectures on infant care, for health visitors, nurses, midwives, and superintendents of infant welfare centres, will be given at the Infants Hospital, Vincent Square, Westminster, on Mondays at 6.30, from January 11th to March 29th.

THE fourth and last of the series of post-graduate lectures on general anaesthesia, arranged by the Dental Board of the United Kingdom, will be given by Professor Noël Paton, F.R.S., and will deal with the metabolic changes in chloroform poisoning. It will be delivered at the Royal Society of Medicine, 1, Wimpole Street, W.1, on January 11th at 8.30 p.m.; in the Medical School, University Buildings, Oxford Road, Manchester, on January 13th at 5.30 p.m.; and in the Surgery Theatre of the University of Edinburgh on January 15th at 5 p.m. No tickets of admission are required.

THE Fellowship of Medicine has arranged a further series of open lectures from January to March on subjects of general interest. Dr. Herbert Spencer will give the opening lecture, on abdominal palpations in pregnancy, on January 21st, at 5 p.m., at 11, Chandos Street, W. From January 11th to 23rd the Prince of Wales's General Hospital will hold an intensive course in general medicine, surgery, and the special departments, with a daily lecture at 4.30 p.m. free to members of the Fellowship. Commencing on January 4th a month's series of lecture demonstrations on psychological medicine has been arranged for Tuesdays and Saturdays, at 11 a.m., at the Bethlem Royal Hospital, and a four weeks' course of lectures and demonstrations in the diagnosis of nervous diseases will begin also on January 4th, at 5 p.m., at the West End Hospital. At the North-Eastern Hospital a three weeks' course in infectious fevers will be given on Wednesdays, at 2.30 p.m., and Saturdays, at 11 a.m., from January 11th to 30th. Whole-day courses have been arranged in diseases of children at the Queen's Hospital and at the National Hospital for Diseases of the Heart from January 18th to 30th. From January 11th onwards there will be weekly demonstrations in clinical surgery; the first will be given at 5 p.m. at St. Mark's Hospital by Mr. Lockhart-Mummery. A copy of each syllabus of the foregoing courses and of the Fellowship general course programme may be obtained from the Secretary, 1, Wimpole Street, W.1.

INTENSIVE courses in cardiology, of a fortnight's duration, are held at the National Hospital for Diseases of the Heart, Westmoreland Street, London, W., in January, July, and October every year; the first course for the year 1926 will commence on Monday, January 18th. The fee for the course, which is limited to sixteen members, is £7 7s. Full particulars may be obtained from the secretary at the hospital.

THE British Institute of Philosophical Studies, of which the Earl of Balfour is president, has arranged for two courses of lectures on science and philosophy, during Lent term, to be given at Bedford College, Regent's Park, N.W.1. The one course (nine lectures), the subject of which is life and mind, will be given by Professor James Johnstone on Mondays at 5.30 p.m., beginning on January 11th. The fee for non-members is £1 5s. The other course (twenty lectures), on the conception of matter, will be given by Professor Leonard J. Russell, and will be given on Tuesdays at 5.30 p.m., beginning on January 12th. The fee is £2 2s. for non-members. Further particulars can be obtained from the Director of the Institute, 88, Kingsway, London, W.C.2.

AN excursion round the Mediterranean in the steamship *Lotus* is being arranged by the *Bruxelles-Médical* from March 17th to April 13th, visiting Naples, Malta, the Piræus, Constantinople, Smyrna, Rhodes, Cyprus, Beyrout, Jaffa, and Alexandria. Land excursions may be arranged to Damascus, Lebanon, Tripoli, Baalbek, Jerusalem, and Cairo, Easter being spent in Jerusalem. The charges for medical practitioners are: first class, 38 guineas; second class, 25 guineas; and third class at reduced rates for medical students. Further information and an illustrated guide may be obtained from Dr. Bernard, 62, Rue Froissart, Brussels.

AT the meeting of the Pharmaceutical Society of Great Britain to be held at 17, Bloomsbury Square, W.C., on Tuesday, January 12th, at 8 p.m., a discussion on some new, modified, and tested formulae of the *British Pharmacopoeial Codex* will be opened by Mr. Frank Browne and Miss Dorothy Randle. Medical friends of members will be welcomed.

THE anniversary meeting of the Royal Anthropological Society will be held at 52, Bedford Place, W.C.1, at 8.30 p.m., on January 26th. A soirée will be held after the transaction of formal business.

MESSRS. J. AND A. CHURCHILL announce for early publication *The Nematode Parasites of Vertebrates*, by Professor Warrington Yorke, M.D., and Dr. P. A. Maplestone. The authors' object has been to provide a trustworthy guide to the allocation of the various parasites to their respective genera. There is an extensive index of generic names and synonyms, an index of specific names, and a copious bibliography. The same publishers will shortly issue a new edition of Professor E. H. Starling's *Principles of Human Physiology*, and the third volume of a new series, entitled *Recent Advances in Obstetrics and Gynaecology*, by Mr. Aleck W. Bourne.

DR. CARLO CHAGAS, director of the Instituto Oswaldo Cruz at Rio de Janeiro, has been appointed professor of tropical medicine in the university of that city.

At the meeting of the Guildford Division of the British Medical Association to be held at the Royal Surrey County Hospital, Guildford, on Thursday next, January 7th, at 4 p.m., Mr. R. P. Rowlands will give an address on the acute abdomen.

The firm of John Wright and Sons of Bristol, founded a hundred years ago, has just issued a centenary souvenir, very elegantly printed and well illustrated, giving an account of the chief events in its history. It has long been the publisher of medical books, but it is, perhaps, best known to the profession through the *Medical Annual*, a very excellent year book, of which the forty-third consecutive issue appeared early last year and was reviewed in our columns last May (p. 845). It prints and publishes also the *British Journal of Surgery* for the committee of surgeons by which that very well got up periodical is conducted. The text and pictures of the souvenir contain an informing sketch of the development of the technical side of printing, and the relation of the firm to medicine is emphasized by pictures of the Bristol Royal Infirmary and the Bristol General Hospital.

The sixth Salon des médecins will be held from March 14th to 24th at 117, Boulevard St. Germain, Paris, for the exhibition of painting, sculpture, engravings, and decorative art by practitioners and students of medicine, dentistry, veterinary science, and their families. Further information can be obtained from the organizing secretary, Dr. Paul Rabier, 84, Rue Lecourbe, Paris, X^e.

PROFESSOR VERTOGEN has been appointed successor of the late Dr. Depage in the Brussels First Surgical Clinic.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9851, 9852, 9853, and 9854** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR of the BRITISH MEDICAL JOURNAL, Antiology Westcent, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER
ate Westcent, London.
ecra Westcent, London.

The **Office of the British Medical Association**
Street, Dublin (telegrams:
Bacillus, Dublin; telephone: 4151 Dublin), and of the Scottish
Office, 6, Drumshugh Gardens, Edinburgh (telegrams: *Associate*,
Edinburgh; telephone: 4361 Central).

QUERIES AND ANSWERS.

INCOME TAX.

Adjustment of Assessment of New Partner.

"G. M. S." entered into a partnership on May 5th, 1925, on the basis of a five-twelfths share, exclusive of prior book debts.

The assessment for the year commencing April 5th, 1925, must be based on the profits of the practice during the three previous years, and will not therefore specifically include either "G. M. S.'s" expenses after May 5th, 1925, or any increased earnings which his work may bring in. His share of the 1925-26 assessment, before deducting his personal allowances, life assurance relief, etc., will be eleven-twelfths of five-twelfths of the amount. He (or his partner) might usefully write to the local Inspector of taxes stating the facts and asking for a note showing how the income tax payable on the 1925-26 assessment should be allocated as between the partners. It is, of course, clear that "G. M. S." may find that he has to pay on more than the net cash received from the practice; that is because he has to account for the tax on his earnings, whether received or not.

TREATMENT OF SPASTIC CONTRACTION IN DISSEMINATED SCLEROSIS.

"PARALYSIS" asks for suggestions for treating a woman, aged 57, suffering from an extreme form of spastic rigidity due to disseminated sclerosis of about ten years' duration. The onset was very gradual, the order of involvement being left leg, right leg, left arm, and now there is increasing diminution in power in the

right arm. The intelligence and general health are unaffected, and syphilis, tuberculosis, and malignancy can be excluded. The pain on the whole has not been very severe, but the pressure and contracture of the left arm over the cardiac region, especially at night, are painful and distressing. Various ingenious pads have been tried. On the form of surgical intervention to giving temporary relief permanent benefit.

There appears to be no published record of surgical treatment for a case of this kind, and possibly systematic massage by a skilled masseuse might give considerable relief. It is important to exclude any cause of local pressure on the cervical cord, since this clinical picture is unusual in disseminated sclerosis, especially the onset at the age of 57.

LETTERS, NOTES, ETC.

DR. A. M. CAYREHILL (Ealing) asks us to state that the credentials of a man giving the name of James Campbell should be examined before money is given to him. He may show a scar of an Eastlander's operation and solicit temporary help.

"IN THE TWILIGHT."

UNDER this title Dr. Duncan Greenlees has recently considered in the *Caledonian Medical Journal* the problem of a steadily enlarging class of sufferers, the "borderland cases." He felt amongst individuals ever since the war a diminished morality, a laxity in all ordinary relationships, and an unhealthy outlook which stands in marked contrast to the healthy and optimistic outlook that previously prevailed. This deterioration he felt expressing itself in the attitude of one country to another—"a sort of political neurasthenia spreading its poisonous germ among the races of mankind who participated in the conflict; a guarded suspicion of each other; an increasing want of confidence in each other's integrity and honesty." In the recent growth of various cults Dr. Greenlees sees evidence of this increasing mental instability, and instances charlatanism outside the profession and faddism within it. He urges the profession whose chief function it should be to educate the public in matters pertaining to their health, actively to combat all such tendencies. From a consideration of these modern "crises" the author proceeds to a study of the approaching march of the psychopathic. He draws attention to the periodicity of such attacks, and regards "psychorhythm" as being observable not only in the alteration of states in the insane and in the borderland cases, but also amongst normal persons—"the ups and downs of normal health." The aggravation in the mental symptoms due to bad physical health or occurring after fatigue is noted, and attention is directed specially to the appearance and recurrence of obsessional states when the subject is suffering from exhaustion. Dr. Greenlees describes the various forms which these obsessions take. For this purpose he divides them into obsessions of indecision, obsessions of fear (the phobias), and obsessions of irresistible impulse; he illustrates his remarks by examples. He considers that the medical man in attendance requires to be temperamentally fitted to undertake the care of such cases, that he must be tactically resourceful, and firm. Removal of the patient from his home and complete freedom from the visits of his friends and relatives is likewise insisted on. The Weir Mitchell treatment, massage, electricity, and dieting are also recommended.

THE ORGANISM OF UNDULANT FEVER.

DR. DANIEL M. MARGUERAT (Malta) suggests that the organism of the disease formerly known as Malta fever might well be renamed "*Bruce's undulococcus*," and that the present title *Micrococcus melitensis*, including its pseudo- and para-varieties should be abandoned, since it is now well known that Mediterranean or undulant fever occurs also in India, South Africa, China, South America, Fiji, and other distant places. The proposed new name for the organism would indicate its discoverer, Sir David Bruce. Dr. Marguerat adds that on December 14th, 1925, the proposed change was suggested to the Minister for Public Health in the Legislative Assembly of Malta.

THE MEDICAL PROFESSION AND UNQUALIFIED PRACTICE.

In a letter in which he expresses dissatisfaction with the conclusions and results of the discussion on the relation of the medical profession to unqualified practice, arranged by the Medical Division, a report of which was published in our issue of December 19th, 1925 (p. 1191), Mr. Paul Bernard Roth, F.R.C. (London, W.1), suggests that before the profession decides on any proper parliamentary action it would be well that an investigation committee should spend a few months in the United States and then draw up a fearless report on osteopathy, regardless of its own prejudices. He proposes that the committee should include a neurologist, an aurist, and an oculist, and be especially interested in the subject.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 44, 45, 48, and 49 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 8.

THE ABSORPTION AND ELIMINATION OF VOLATILE SUBSTANCES THROUGH THE LUNGS:

ANAESTHESIA, POISONING BY GASES AND VAPOURS
IN INDUSTRY, TREATMENT OF ASPHYXIA.*

BY

YANDELL HENDERSON, Ph.D.,
PROFESSOR OF APPLIED PHYSIOLOGY, YALE UNIVERSITY.

THE art of anaesthesia is usually treated as if its scientific basis were distinct and peculiar. In fact, however, the inhalation of volatile substances, gases or vapours with strong pharmacological actions, is not confined to anaesthesia. We have used illuminating gas in our houses, and have inhaled at least its combustion products for two generations past; and now the motor car adds its exhaust gas to the air we inhale in the streets. Petrol is an anaesthetic, although a poor one.¹ The use of gases in war; the increasing pollution of the atmosphere with the gases and vapours of industry; the use of oxygen in the treatment of pneumonia—all of these are subjects which have points in common with inhalational anaesthesia. I propose in this lecture to refer to such collateral subjects, for the sake of the information and experience that can be extracted from them, throwing light on the art of administering a volatile anaesthetic.

The Importance of Volatility:

It is no mere accident that the substances which we use as anaesthetics for surgical purposes are volatile. There are, indeed, non-volatile anaesthetics, solids and liquids. They find use in experimental work on animals when the subject is not to be kept alive. But with the exception of morphine, which is scarcely an anaesthetic, they are not used to any extent upon patients. Why is it that in general the volatile anaesthetics are preferred to those which are non-volatile? The answer is, I think, that for surgical anaesthesia the patient must be very profoundly drugged—more profoundly than in any other condition for which drugs are used; so profoundly, in fact, that death would almost inevitably follow if the condition were continued for many hours. The fact that the substances used as anaesthetics are volatile enables them to be absorbed extremely rapidly up to the high concentration in the blood necessary for an anaesthetic action upon the nervous system. Their volatility also allows a more rapid elimination than is possible for any non-volatile substance.

Volatility, the property of forming a gas or vapour, is a quality of the utmost importance in determining the physiological effects of substances that may gain entrance to the body, or to which the body may be exposed. Volatility renders a substance capable of entering and leaving the body through the lungs. The differences between absorption and elimination through the lungs, on the one hand, and, on the other hand, absorption from the alimentary canal and elimination through the kidneys, are of far-reaching but not generally appreciated significance. There are in chemistry and physics certain much used principles called the gas laws: the laws of Boyle, of Henry, and of Charles. These laws have no direct bearing upon absorption from the stomach or excretion through the kidneys, and little application therefore to solids and liquids. We do not yet know with any degree of precision the laws controlling absorption from the stomach and intestines and excretion through the kidneys. But the gas laws dominate absolutely, in respect to the absorption and elimination of volatile substances through the lungs, and afford the foundation for the toxicology, the pharmacology, and the therapeutics of gases and vapours.

A substance taken in through the lungs may act so much more rapidly and intensely than when taken in through the stomach that it is hard to believe that the cause in the two cases is the same substance. As an illustration let us take lead. Ordinarily, lead poisoning, as seen in painters,

type-setters, and other trades, is a slowly progressing chronic condition affecting the teeth, the alimentary canal, and some voluntary muscles. Recently it was discovered that a compound of lead with some organic groups, in particular tetra-ethyl lead, which is a volatile liquid, has the property of greatly increasing the efficiency of motor-car engines. The addition of only 0.1 per cent. of this substance to gasoline or petrol is sufficient to alter the character of the explosion in the cylinders of the engine, so as to afford a much smoother working and a possibility of greater efficiency. Following up this discovery a combination of the largest industrial concerns in America undertook to manufacture and sell this material. We sanitarians, who are more interested in the welfare of the human machine than in greater efficiency in motor-car engines, protested that an immense industrial and public health hazard would be involved in such a use of lead; and we have succeeded in having the whole matter referred to a commission for study. But the point that I wish to call to your attention is that at nearly every stage of the development, manufacture, and distribution of this substance there were outbreaks of poisoning. The symptoms of poisoning by this volatile lead compound were, however, quite unlike ordinary lead poisoning. Even physicians with the widest experience in industrial diseases were at first inclined to deny that the fatalities were essentially due to lead. The sequence of symptoms was usually insomnia, visual delusions, and violent mania, soon leading to death. Encephalitis and mania are, indeed, described in the literature, but are seldom seen, as the result of the swallowing of lead. The inhalation of lead dust usually induces the slow form of poisoning. But when lead in a truly volatile form is inhaled the effect is acute, and is primarily upon the brain.²

These facts illustrate the difference between the effects of the absorption of lead or any other substance from the alimentary canal, and absorption from the lungs. It is scarcely possible, or at least exceedingly rare, for absorption from the stomach to be so rapid as to produce simultaneously the same concentration or pressure of a soluble substance in the stomach, in the arterial blood, and in the brain. But we have learned that with a large number of volatile substances the natural and usual relation is that the pressure and concentration of the substance in the lungs instantly produce the same pressure and a corresponding concentration of the substance in the arterial blood, and almost immediately the same pressure and concentration of the substance in the brain. Absorption from the lungs is not only more rapid than from the stomach, but more rapid than from subcutaneous injection, and practically more rapid even than from intravenous infusion.

As regards the elimination of any substance, the lungs are incomparably the most rapid channel. A substance which, even with the aid of diuresis, will be excreted through the kidneys only in the course of days, may be excreted through the lungs within a few hours. The lungs should, therefore, be used for the therapeutic elimination of all harmful substances that are volatile. The method of increasing the volume of breathing so as to obtain a maximal pulmonary ventilation for such therapeutic purposes was described in my previous lecture.

If a further illustration is needed, it is afforded by a comparison of ethyl ether with ethyl alcohol, the latter in the form of Scotch whisky. The pharmacological actions of ethyl alcohol and ethyl ether upon nerve tissue are fundamentally almost the same. But how different are the common uses of the two liquids! How different are the commonly observed effects upon the users induced by the two substances! Alcohol is indeed capable of being burned to some extent in the body; ether is not. But fundamentally it is not this property that produces the differences between the symptoms, the intensity, and the duration of alcoholic drunkenness and ether anaesthesia. Essentially the differences in the two conditions are due to the facts (1) that ether is far more volatile than alcohol, (2) that alcohol is far more soluble in blood than ether, and is therefore less rapidly ventilated out of the blood in the lungs, and (3) that it is customary to take alcohol in liquid form into the stomach, while ether is taken in vapour through the lungs.

* The second of two lectures under the auspices of the Dental Board of the United Kingdom, delivered at the Royal Society of Medicine, London, October 23rd, 1925. The first lecture was published in the JOURNAL for December 19th, 1925 (p. 1170).

Applications of the Gas Laws.

Recently Haggard and I³ have formulated the applications of the gas laws in this field. We have confirmed and amplified the conclusion reached by Cushman.¹⁴ Without attempting to go too much into detail I may here give you a summary of the principles at which we have arrived and which control the absorption, distribution, and elimination of what we may call non-reacting gases. By a non-reacting gas we mean one which is taken up, held, and given off again by the blood and tissue fluids of the body in simple solution, which undergoes no alteration in the body, but is both absorbed and eliminated simply by diffusion from and into the air of the lungs and into the urine. It may or may not have pharmacological action. Examples of such gases are nitrogen, methane, and ethyl ether. The first has been studied by Haldane, Boycott, and Damant,⁴ in relation to caisson disease, the compressed-air illness of deep-sea divers. Ether has recently been investigated from this standpoint by Haggard. The absorption and elimination of such gases depend upon four main factors.

1. The rate at which a gas is absorbed into the body and the amount the body can hold vary greatly according as the gas is more or less soluble. In general, the solubility of a gas in blood is only slightly less than its solubility in water. Its solubility at the temperature of the air in the lungs determines its behaviour. The capacity of the various tissues to dissolve gases varies widely; it is low in bone and often very high in fat; but with most gases the average for the body as a whole is probably nearly the same as the solubility in blood. This, at least, is true of ether, as Haggard has found. The total amount of any gas that the body will take up is dependent both upon its solubility and upon the concentration in the air breathed.

2. The rate of absorption is directly proportional to the concentration of the gas or vapour in the air breathed. The concentration in the air is generally best expressed in milligrams of the substance per litre of air. The concentration that is effective is, however, not exactly the concentration in the air of the room; it is the concentration when the air is warmed to body temperature and saturated with moisture. It is the somewhat reduced concentration under these conditions, as they obtain in the lungs, which induces diffusion into the blood passing through the lungs. At the saturation point the total amount of the gas in the body is directly proportional to the concentration in the atmosphere, with which the blood and body as a whole have come into equilibrium. From twice as high a concentration the body will absorb twice as much of the gas.

3. The third factor determining the rate of absorption is the pulmonary ventilation. It depends upon the volume of air breathed, and the amount of the gas thus brought into contact with the blood in the lungs, but not that which merely enters the dead space. As we shall see, respiration is particularly important in respect both to absorption and elimination in the case of quite soluble gases and vapours, such as ethyl ether; but it is comparatively unimportant in respect to relatively insoluble gases, such as nitrogen.

4. The circulation is the fourth factor, and is largely determinative of the rate of absorption and elimination of gases of relatively low solubility, while for such gases respiration plays a comparatively small part. Thus a condition which would double the volume of air breathed per minute would only slightly affect the entrance or exit of such a gas, so long as the circulation remains constant. But if the circulation were doubled, so that twice as much blood would flow through the lungs each minute, even with respiration unchanged, the rate of absorption and elimination of such a gas would be nearly doubled.

For the various factors concerned in these processes and conditions we use the following symbols:

L = Effective pulmonary ventilation in litres per minute—that is, respiration minus the volume of air which merely enters the dead space.

C = Concentration of the gas in milligrams per litre of inspired air, when warmed to body temperature and saturated with moisture as it is in the lungs.

K = Coefficient of distribution of the gas between equal volumes of lung air and pulmonary blood. For ordinary conditions complete and instantaneous equilibrium between arterial blood and lung air may be safely assumed. Thus, if for a certain gas such as the

vapour of ethyl ether K is 15, this figure means that there is always in the blood leaving the lungs, and in the arterial blood, 15 times as much of that gas in one litre of blood as in one litre of alveolar air; and that this holds true alike during absorption, equilibrium, and elimination of the gas.

G = The volume of blood, expressed in litres or kilos, in active circulation in the body—in other words, the effective blood volume at the time.

B = Circulation, defined as the number of litres or kilos of blood flowing through the lungs in one minute.

A_c = Concentration of the gas in the arterial blood in milligrams per litre.

V_c = Concentration of the gas in the mixed venous blood in the right heart in milligrams per litre.

W = Body weight in kilos.

Using these symbols we derive the following expressions:

(1) LC = the amount of the gas inhaled into the lungs per minute.

(2) $LC \times \frac{L}{BK + L}$ = amount of the gas again exhaled from the lungs per minute.

(3) $LC \times \frac{BK}{BK + L}$ = amount of the gas absorbed per minute into the blood, before any of the blood completes the round of the circulation, and returns to the lungs from the venous side—that is, the initial rate of absorption.

(4) $\frac{LCK}{BK + L}$ = amount of gas in milligrams absorbed per litre of blood flowing through the lungs.

(5) $\frac{LCKG}{BK + L}$ = amount of gas absorbed during the first complete circulation of the blood, which is accomplished in the time $\frac{G}{B}$, a period less than one minute even during bodily rest.

(6) $\frac{LCKG}{BK + L} \times \frac{G}{W}$ = amount of the gas brought back to the lungs by the venous blood during the second round of the circulation.

The amount of the gas which the blood brings back to the lungs from the venous side is added to that which the breathing takes into the lungs, and the sum of the two quantities is distributed between the arterial blood and the expired air in accord with their relative volumes and with the coefficient of solubility. The distribution is always in the ratio $BK : L$.

These expressions signify that during absorption the arterial blood contains at first far more of the gas or vapour than the venous blood. But as the inhalation of a constant concentration of a gas in the air continues, the concentrations in the arterial and venous blood gradually approach the same value—namely, that of saturation for the concentration of the gas in the air. At all times the mixed venous blood flowing back from the body contains an amount of the gas per litre which is the same as the average concentration in the body as a whole at the moment (in milligrams of the gas per kilo of body weight). During absorption, therefore, especially in the earlier stages, the concentration in the venous blood is far below that in the arterial blood. During elimination, on the contrary, the venous blood has a concentration which is the average of the concentration in the body as a whole, while that of the arterial blood is lower than the venous by the fraction thrown off in the breath. Thus

(7) $V_c \left(1 - \frac{L}{BK + L}\right) = A_c$, the arterial concentration during elimination.

The amount of any gas that the body will hold is defined by the expression:

(8) CKW = amount of gas in the body at equilibrium with C in the air.

Evidently the maximum amount of a gas that can be absorbed is not a fixed absolute quantity, but is proportional to the concentration of that particular gas in the air. When respiration and circulation remain uniform and normal, the rate of absorption is such that, if a certain percentage of saturation is taken up in one minute, the same percentage of the remaining unsaturation will be absorbed in the second minute, and so on thereafter. Thus if saturation be taken as 100 and if 1 per cent. of this amount is absorbed in one minute, 1 per cent. of 99 will be absorbed in the second minute; and 1 per cent. of 98.01 in the third minute, and so on. The absorption is thus comparatively rapid at

first, then slower, and finally infinitely slow. It is not practical, therefore, to determine the time when equilibrium of intake and elimination will be reached, but it is often convenient for purposes of calculation to use the time required to reach 50 per cent. saturation, $\frac{CKW}{2}$, or some other percentage of saturation.

If we let t_x represent the time required to reach the percentage of saturation x , we may calculate this time in minutes by means of the expression

$$(9) \quad t_x = \frac{2.3 \times W(BK + L)}{LB} \log \frac{1}{1-x}.$$

The use of the half-saturation time, or the time of any definite percentage of saturation, is particularly convenient because it is the same for all concentrations of any one gas, so long as respiration and circulation are uniform. But the greater the solubility of a gas, the longer is the time required to reach half-saturation, and the greater the absolute amount constituting half-saturation.

For an average human adult at rest with normal volume of respiration and circulation, the time of half-saturation for a gas or vapour of $K=15$, such as ethyl ether, is about two and a half hours, while for one of $K=0.014$, nitrogen, it is about seven minutes, and for 90 per cent. of saturation about twenty-two minutes. For a child, owing to the more active metabolism and greater relative volume of breathing and circulation in relation to body weight, the time required to reach half-saturation, or any other definite percentage, is correspondingly less. The same relation holds true in an adult when respiration and circulation are increased by exercise, or by the pharmacological action of the gas itself, or in any other way.

The absorption of any absolute amount of gas—for example, the anaesthetic amount of ether—is effected very slowly when a low concentration of the gas is inhaled, but with a far more than proportional rapidity when the concentration in the air is high. The rates of absorption are not expressed by straight lines, but by exponential curves, which rise rapidly at first and then more and more slowly. In the absorption curves of all concentrations of a given gas points having equal abscissae have ordinates which are proportional to the concentrations. An absolute amount in millilitres may therefore be only a relatively low percentage of the saturation limit (CKW) of a high concentration, but a high percentage of the limit, or even exceed the limit, for a low concentration.

The influence of respiration, circulation, and the solubility of the gas upon the time required to reach 50, or any other, per cent. of saturation is expressed by the formula:

$$(10) \quad \frac{t_x}{t'_x} = \frac{\frac{BK+L}{LB}}{\frac{B'K'+L'}{L'B'}}.$$

Using this formula and substituting various values of K , so as to see the effect that solubility has, not only on the rate of absorption but also on the parts played by respiration and the circulation in effecting absorption, we reach results of great utility. Thus with a gas of a solubility as low as 0.01, even a doubling of the respiration scarcely affects the rate of absorption or of elimination, while a doubling of the circulation of the blood induces a nearly proportional increase of the rate of absorption and elimination. On the other hand, with a gas of solubility 10, alterations of the circulation of the blood have an entirely negligible effect, while the rates of absorption and elimination rise and fall almost in proportion to the volume of respiration. This is shown in the following table.

	B=B'=1.		L=L'=1.	
	L=1.	L'=2.	B=1.	B'=2.
K=0.01	$\frac{1.01}{1}$	$\frac{2.01}{2}$	$\frac{1.01}{1}$	$\frac{1.02}{2}$
"				
K'=10.0	$\frac{11}{1}$	$\frac{6}{1}$	$\frac{11}{1}$	$\frac{21}{2}$

Irritant Gases.

From the standpoint of a physician interested in industrial diseases, and from the standpoint of the use of gases in war, the irritant gases have a peculiar importance. For us, in connexion with the topic of this lecture, irritation of the lungs is chiefly of interest because it occasionally follows ether anaesthesia. Ether vapour in high concentration is well known to be an irritant. If, then, sufficiently large amounts of ether are to be introduced into the lungs without resorting to very high concentrations in the inhaled air, there is obviously only one way to effect the purpose. This is by increasing the volume of air breathed by means of an inhalation of carbon dioxide as a preliminary to the initiation of anaesthesia.

The laws of absorption which we have just now considered teach us that if the ventilation of the lungs is increased to twice its ordinary amount, and the concentration of the inspired ether vapour is reduced to one-half, we may induce the absorption of the same amount of ether as is effected by a small volume of breathing and a high concentration of the vapour in the inspired air. The first combination avoids the irritant action of ether on the lungs, the second subjects the patient to it.

In general the effects of the irritant vapours follow a law worked out in my laboratory by Haggard.⁵ This law is that the more soluble the gas the more it attacks the upper respiratory tract; the less soluble it is the more liable it is to act chiefly upon the deeper parts—the bronchi and the lungs. The more soluble substances, such as ammonia, are largely absorbed on the damp walls of the nares, pharynx, larynx, and trachea. They also excite the respiratory reflexes of coughing and closure of the glottis; and the lungs are thus protected. With substances such as phosgene and the higher oxides of nitrogen the comparatively slight solubility and relatively slight immediate irritation allow the chief action to be effected in the lungs themselves. So the patient may feel quite well for some hours afterward, and then develop an acute pulmonary oedema and die on the slightest exertion.

The nature of pulmonary congestion and oedema is still obscure, and the causal connexion of anaesthesia and post-operative pneumonia is not wholly clear. I suspect that if the lungs of patients were regularly examined every few hours for a day or two after anaesthesia, râles and other indications of irritation would be found in a considerable proportion of cases, even among those who fortunately recover without developing pneumonia. It is well recognized, as the result of observations on gassed soldiers during the war, that asphyxia is a consequence of the congestion and oedema of the lungs induced by irritant gases. It is not generally realized that the opposite relation is also possible, and that asphyxia, even partial asphyxia, may induce severe pulmonary effects, even when the gas causing the asphyxia has in itself no direct irritant action whatever. Thus it was found by David⁶ that mere oxygen deprivation by excess of nitrogen may induce pulmonary congestion in animals. We have found that in dogs slowly asphyxiated with carbon monoxide the congestion of the lungs may be so acute that a lobe of lung is scarcely distinguishable at first glance in its density and colour from a lobe of the liver, so intense is the congestion. Yet it is absolutely certain that carbon monoxide is entirely devoid of direct irritant action.

Of course, pneumonia following anaesthesia is a bacterial infection; but without a predisposing disturbance of physiological conditions the lungs would resist the invasion and infection. We cannot assign with certainty the relative importance of such factors as the chill induced by ether, when volatilized on an open mask, the irritation induced by highly concentrated ether vapour in the lungs, the anoxaemia and acapnia, and the slow emergence from coma, all characteristic of a vast number of anaesthetics. But this aspect of the matter I would emphasize: that all of these hazards may be eliminated together by the procedures described in my previous lecture.

Carbon Monoxide Asphyxia.

I cannot urge too strongly that the study of anaesthesia, at least with volatile anaesthetics, is merely a branch of

a larger subject—that of gases and vapours in their physiology, toxicology, therapeutics, and industrial and sanitary aspects. Sanitary science has a vast fund of knowledge regarding foods, water supplies, and corresponding subjects; and this knowledge is now extensively applied. But it is only recently that pollution of the air that we breathe has begun to receive adequate consideration. My reason for directing attention to this matter now is that all phases of the physiology of gases are mutually contributory. Anyone interested in the volatile anaesthetics will profit by including some acquaintance with the industrial gases. So I propose to devote the remainder of this lecture to certain aspects of carbon monoxide as it now affects the lives of all civilized men.

It is well established that the number of deaths each year in any city due to its illuminating gas rises in direct proportion, or even in more than direct proportion, to the amount of carbon monoxide in the gas. In those cities where coal gas of low carbon monoxide content is supplied asphyxiations are few. In New York City at the other end of the scale, where the gas contains nearly 30 per cent. of carbon monoxide, the number of deaths from carbon monoxide asphyxiation runs up toward 500 a year. A part, but only a part, of this mortality is suicide; the despondent New Yorker turns on the gas, just as a despondent Londoner jumps into the Thames.

In recent years the automobile has enormously increased our exposure to carbon monoxide. But knowledge has been accumulated now which we may at least hope will provide the basis for much needed reform. In America tunnels are being introduced, particularly in New York, where the Hudson River is nearly three-quarters of a mile wide; too wide for bridges and inconvenient for ferries. The ventilation of such a tube, with a double line of vehicles moving through it, raised special problems. The chemical aspects of these problems were referred to Mr. A. C. Fieldner⁷ of the United States Bureau of Mines, while the physiological aspects were referred to me for investigation. Mr. Fieldner and I, and our co-workers, developed a standard for tunnel ventilation, which has been adopted, not only in America but also in England, on the advice of Dr. J. S. Haldane, for the tunnel to be constructed under the Mersey River at Liverpool. Experience in a similar tunnel at Pittsburgh, Pa., has now demonstrated the safety of this standard, and the danger (before ventilation was installed) in failing to maintain it.

FIG. 1.—Showing the relation of carburettor adjustment in the ratio of air to gasoline (petrol) to efficiency, power, combustion of fuel, and amounts of carbon dioxide and carbon monoxide produced in an automobile engine.

The sum and substance of Fieldner's very extensive tests on a large number of passenger cars and trucks are summarized in Fig. 1. It shows at a glance the general behaviour of the motors now used in automobiles and the extent to which the fuel is consumed. Roughly, in any one car, the distance travelled, the number of strokes of the engine, and the amount of air drawn into and discharged from the cylinders are proportional quantities. So

the greater the amount of fuel in proportion to air—that is, the richer the mixture to which the carburettor is set, the greater the fuel consumption per mile and the less the efficiency. Unfortunately the richer mixtures afford greater power, especially for starting and hill climbing; and carburettors are usually set to deliver a pound of fuel for each 12 lb. of air. If the manufacturers and the owners of motor cars were truly interested in saving fuel the engines could be adjusted to an efficiency requiring only 1 lb. of fuel to each 15 lb. of air. The saving of fuel would amount to 20 or even 30 per cent.

FIG. 2.—Showing the carbon monoxide dissociation curve of blood (solid line) and the percentage saturation after one hour in various concentrations of the gas (broken line).

We might leave this whole matter to engineers for solution, except for the fact that it also involves a health hazard which is reaching serious proportions. With a full supply of air the combustion in an explosion engine may be nearly complete; its products in that case are carbon dioxide and water vapour. With the excessively rich mixtures habitually employed the combustion is, on the contrary, extremely incomplete; one-third of the fuel value is unconsumed. Thus, as shown by the straight lines which cross in the figure, the proportion of carbon dioxide decreases rapidly and that of carbon monoxide increases rapidly with the richness of the mixture. As we see in the figure, exhaust gas usually contains about 6 per cent. of carbon monoxide, an amount which, if discharged in any quantity into a confined space, is intensely poisonous. It is not merely this concentration, but rather the absolute amount of carbon monoxide that is important. The amount is approximately 1 cubic foot per minute for each 20 horse-power. This means that from even the smallest car commonly used in America there is enough carbon monoxide to render the atmosphere of a small closed garage of 10 by 10 by 20 feet deadly in less than ten minutes. As is well known, the victims of carbon monoxide poisoning often lose the power to stand or walk before any other symptom warns them of their danger. Neglect to open the garage doors before starting a car is thus an increasingly common cause of death in spite of extensive public warnings.

In the physiological part of the investigations we first studied in detail the fundamental matter of the combination which carbon monoxide makes with the haemoglobin of the blood and the general nature of carbon monoxide asphyxia. Our observations verified in every detail the fundamental work of Haldane. We then proceeded to determine the rate at which men and women exposed to atmospheres contaminated with exhaust gas will absorb carbon monoxide, and the physiological effects of various amounts for periods of one hour.³

The results of these investigations are expressed graphically in Fig. 2. Here the upper curve is the well known theoretical dissociation curve of carbon monoxide and haemoglobin in the presence of air; the lower curve expresses very practical information as to the approximate percentage of saturation that a man will develop in one hour, if he is sitting still in an atmosphere containing the amount of carbon monoxide shown in the scale below the abscissa. This curve and the scale are drawn for a normal volume of breathing. If respiration were doubled these percentages of saturation would be attained in half an hour.

and the curve would therefore represent the percentages of saturation attained in this time by a man breathing air containing the amounts of carbon monoxide indicated.

On this basis I recommended 0.04 per cent., or 4 parts of carbon monoxide in 10,000 of air, as the maximum concentration allowable in air to be breathed for such a period as that required to pass through the Hudson River tunnel, a period probably of a quarter to half an hour. As this standard has been very widely adopted, it is important that I should emphasize the fact that it applies only to quite short periods of time. Any standard for the contamination of air with carbon monoxide must specify, not only the amount of carbon monoxide, but also the time of exposure. Thus the full sanitary rule which we developed is as follows: When the time of exposure is measured in hours and the concentration is measured in parts of carbon monoxide per 10,000 of air, then if the product of the time multiplied by the concentration equals 3, no perceptible physiological effect results. If the product equals 6, there is a just perceptible effect, perhaps a slight headache and lassitude; if it equals 9, severe headache and nausea result; if it equals 15 the condition is dangerous; if it rises above 15, the conditions are such as will be quickly fatal. If the subject is making any muscular exertion and his breathing is increased, the figures for the products of time and concentration that are comfortable and safe are reduced from 3 to 2, or 1, or even less; for the rate of absorption varies directly with the volume of the breathing.

Conditions in Streets and Garages.

With this rule in mind we proceeded to determine the extent of the contamination of the air in the streets of New York City, where traffic is congested.⁹ The general results of our investigations show that concentrations of 1 part of carbon monoxide in 10,000 of air are rather common, and indicate that the conditions in crowded streets are on the verge of being definitely injurious for persons who are exposed in them for many hours. In garages the conditions are often far up in the scale of unhealthiness, and headaches are common.¹⁰ The conditions in assembling and repair shops are much worse; indeed, they are so bad that the mechanics have severe asphyxial headaches, often accompanied by nausea and extreme unreasonableness of temper, several times each week. Altogether the automobile trade in America is one of the most unhealthy in modern industry.

To a considerable extent these conditions are unnecessary. The carburettors and engines of cars could be adjusted so as to conserve fuel and decrease the amount of carbon monoxide produced. While Governments are gravely considering the world's dwindling supply of petroleum, the manufacturers of cars have as yet done little to help in overcoming the serious health hazard involved in the wasteful consumption and incomplete combustion of petroleum products. It is, indeed, surprising that when all automotive engineers know that a slight change and a negligible increase of cost would effect such great improvements, conditions are allowed to continue as wasteful and as unhealthy as they are in America now. Owing to the general use of less highly powered cars here in Great Britain conditions seem to be distinctly better. In my opinion, the high tax here of £1 per year per rated horsepower is a measure of distinct sanitary advantage.

Pending more fundamental improvements, there is a device by which the air in streets, and especially the conditions in garages and repair shops, could be greatly improved. This device is the so-called vertical exhaust. It involves merely a continuation of the exhaust pipe vertically upward at the back of the car so as to discharge the exhaust gases upward out of the level at which we inhale air through our noses and mouths. A vertical exhaust pipe is in effect merely a chimney. To discharge exhaust gas below a car in the manner now customary has the same disadvantage that would be produced if all stoves and furnaces were vented through basement windows. It is just as important to employ the ancient device of the chimney upon motor cars as it is upon locomotives and other engines. Although exhaust gas is a relatively colourless form of smoke, its constituents are actually more toxic

than are those of most of the smoke produced from the burning of coal. I believe that, with the increasing use of cars, vertical exhaust will ultimately be required, at least on all city taxicabs and omnibuses.

The Elimination of Carbon Monoxide from the Blood.

Finally, I wish to return for a few minutes to a topic to which I referred also in my previous lecture: the treatment of acute carbon monoxide poisoning. Within a few hours after profound but not fatal poisoning with carbon monoxide no trace of the gas is found in the blood. It has been eliminated through a reversal of the process through which it was absorbed. And yet for days, months, and even for life, structural degenerations and functional derangements, usually either nervous or cardiac, may continue. They are the sequelae of the injury wrought by oxygen deficiency and its concomitants, while the gas was still in the victim's blood.

The investigations to which I have already referred drew our attention to the question of the rate at which the gas is eliminated. Haggard and I¹¹ thus came upon a point which had previously been overlooked and which suggested the therapy—perhaps it should rather be called a prophylaxis—which has come into extensive use. We had previously determined the rate of elimination of carbon monoxide in men who had reached saturations of 20 or 30 per cent. Haldane has recorded the rate of elimination after saturations of 40 or even 50 per cent. His data and ours both indicate an elimination during the first hour of about one-half the amount of carbon monoxide previously absorbed. No one, however, had studied the rate at which carbon monoxide is eliminated during the first hour or two after a gassing which has produced a saturation of the blood of considerably more than 50 per cent. with coma and its accompaniments. There is a fundamental difference between the behaviour of subjects gassed to the point of coma and that of those in whom the saturation does not exceed 50 per cent., and the duration of exposure is not prolonged. Under the latter conditions the subjects breathe practically normal volumes of air, and their metabolism at most is only slightly perverted.

Our observations on subjects more profoundly poisoned soon showed that when the degree of saturation of the blood rises to figures above 50 per cent. and definite asphyxia is threatened, there is excessive breathing which markedly reduces the body's store of carbon dioxide. We found that when the victim is afterwards removed from the poisonous atmosphere the breathing, lacking its normal stimulus, remains at a very low level for an hour or more. The body lacks the carbon dioxide needed to maintain an efficient ventilation of the lungs. The elimination of carbon monoxide during this time is therefore very slight. Although the body is surrounded by fresh air the asphyxiation continues within the tissues. Even the administration of oxygen has no great effect, for it is not adequately inhaled. Until a sufficient amount of carbon dioxide is reaccumulated in the blood and tissues efficient breathing does not return, and the injurious conditions within the living cells of the nervous system and heart are thus continued long after the body is surrounded by pure air. When, as in our experiments, the period of gassing is brief but acute, most of the asphyxia, during which the harm is wrought, probably occurs after the subject is removed from the poisonous atmosphere. It is largely during this time that the autolytic and necrotic processes are so intensified as to be thereafter irreversible. Evidently the abbreviation of the post-gassing period of depressed breathing and its continued asphyxia are of critical importance in preventing permanent damage.

Dogs were used in our experiments. They were placed in a glass-walled gassing chamber through which was passed a current of air and enough city illuminating gas to produce a concentration of 0.3 to 0.4 per cent. of carbon monoxide. Up to the point of unconsciousness the picture presented by the subjects resembled closely that of slow anaesthesia with ether. At first the animals were restless, then a stage of excitement set in, followed by muscular weakness. Respiration became more and more vigorous, culminating as coma developed in violent and prolonged hyperpnoea.

After five or ten minutes of unconsciousness the animals were removed from the gassing chamber, and at frequent intervals thereafter for a couple of hours small samples of blood were taken and analysed for carbon monoxide. The experiments fall into four groups: (1) those in which the subjects were allowed to recover spontaneously; (2) those in which they were made to inhale oxygen; (3) those in which they were made to inhale air to which 8 to 10 per cent. of carbon dioxide had been added; (4) those in which they were made to inhale oxygen containing 8 to 10 per cent. of carbon dioxide.

The results of these four groups of experiments are shown by the curves in Fig. 3. It is here seen that animals left

Fig. 3.—Showing the rate of elimination of carbon monoxide from the blood in dogs, (a) untreated, (b) under inhalation of oxygen, (c) air and CO₂, (d) oxygen and CO₂.

to recover spontaneously have a very slow rate of elimination during the first half or three-quarters of an hour. In those treated with oxygen the elimination is at first scarcely more rapid, for the animals do not breathe any better; indeed, in some cases they breathe even less when oxygen is administered than when they are left to recover spontaneously. Such slight benefit as pure oxygen affords is seen in the greater rapidity of elimination in the latter part of the first hour, or the first part of the second hour. With inhalation of air and carbon dioxide, as in the third group of experiments, the curve starts downward immediately and falls in a practically straight line. This is due to the increased respiration, which provides sufficient fresh air to start the elimination of carbon monoxide immediately. Finally, the fourth curve shows that under inhalation of oxygen containing carbon dioxide the blood of the subjects was practically freed from carbon monoxide within twenty minutes. The augmented breathing and high concentration of oxygen together rapidly displace carbon monoxide from the blood.

Later we were able to follow essentially the same sequence of events in the human victims of gas poisoning.¹² Both the hyperpnoea during gassing and the depression of respiration after removal from the poisonous atmosphere were verified. The slow elimination during the first hour or two has been verified in patients who received no inhalation, while, on the contrary, rapid elimination was found in all cases where a mixture of oxygen and carbon dioxide was administered. The mixture generally employed is 5 per cent. carbon dioxide and 95 per cent. oxygen. This treatment has now saved a large number of lives, and has come into very general use in America. In two respects its benefits have exceeded even our hopes. It seems to prevent the subsequent development of pneumonia, a fact which is probably due to the overcoming of the initial pulmonary congestion. The treatment has also proved capable of effecting complete restoration without subsequent nervous sequelae even in patients gassed for considerable periods. Its most brilliant successes, however, have followed applications to men who have been gassed acutely but for short periods of time, as in the case of workmen exposed to the

fumes from blast furnaces, or those overcome by illuminating gas while working in a sewer or a trench in the streets, or men in the city fire brigade, who, as they say, have been "eating smoke" while fighting a fire. In such cases the subject may have been not only unconscious, but so nearly dead that artificial respiration was necessary at the beginning of the inhalation, and yet after fifteen or twenty minutes' inhalation he is in many cases not only conscious and breathing naturally, but able to get on his feet and go back to work.

In preparing for the treatment of poisoning by the various gases and vapours of modern industry the question sometimes arises whether to provide cylinders containing the mixture of oxygen and carbon dioxide, or merely carbon dioxide to be mixed with air as it is wanted. For all those volatile poisons which cause the blood to be deficient in oxygen, inhalation of oxygen and carbon dioxide is superior to air and carbon dioxide. But the intoxications which cause no oxygen deficiency can be treated with air and carbon dioxide quite as effectively as with oxygen and carbon dioxide, and infinitely better than with oxygen alone, as in the past. Even for treating asphyxial cases in some industries here in Great Britain, air and carbon dioxide probably offer some important practical advantages over oxygen and carbon dioxide.¹³ Carbon dioxide is relatively cheap, and the supply of one cylinder lasts much longer than a cylinder of oxygen and carbon dioxide. For the many non-asphyxiant volatile toxic substances to which modern man exposes himself (for example, various alcohols, petroleum products, benzole, etc.) air and carbon dioxide are the logical and effective antidote. The aim is to stimulate the breathing of the patient, and to maintain it for an hour or more at such a large volume as will ventilate the poison out of the blood by way of the lungs, and thus clear the body and especially the brain. Oxygen does not stimulate respiration; carbon dioxide does.

CHANGE OF TENSION ON THE LENS CAPSULES DURING ACCOMMODATION AND UNDER THE INFLUENCE OF VARIOUS DRUGS.*

BY

BASIL GRAVES,

SURGEON, ST. PAUL'S EYE HOSPITAL, LIVERPOOL; TEMPORARILY, POST-GRADUATE CLINICAL LECTURER, DEPARTMENT OF OPHTHALMOLOGY, BELLEVUE HOSPITAL, NEW YORK UNIVERSITY, ETC.

A PATIENT came in 1924 wearing glasses for his one sound eye. I questioned him about the other eye which does not, unaided, possess useful sight; no evidence of the presence of a lens can, by ordinary methods of examination, be seen in this eye which has absolutely clear media and normal (6/5) vision with a plus 14 lens. The slit-lamp reveals the following features: A tiny scar-track (C, Fig. 1) through the cornea; at the bottom of the anterior chamber a tiny brown spherical object (X) which is doubtless an encapsulated or partially disintegrated minute foreign body; a minute prick (K) in the pigment-layer of the iris at the pupil-margin opposite the corneal scar; and finally, opposite this, a small rather oval hole (a) in an absolutely clear and otherwise intact anterior lens-capsule (A). The posterior lens-capsule (P) is equally clear and wholly intact, and vestige of lens-matter remains between these two clear, and thin capsules: it has all dissolved out with a completeness

* Read by invitation on May 6th, 1925, before the sixty-first annual meeting of the American Ophthalmological Society, Washington, D.C.

which may be appreciated by the fact that the media are absolutely clear to careful examination with the retinoscope or even to close focused examination with the direct electric ophthalmoscope and its *plus* 12 to *plus* 20 lenses.

Aqueous fluid occupies the intracapsular space which is thrown into communication with the anterior chamber by means of the small hole in the anterior capsule.

My full notes on this case are in England and I have written this paper from an abstract which I have brought with me to America. I cannot now give exact measurements which are of no particular importance, but as far as I can calculate from some of the data in this abstract the elliptical corneal scar measures at the endothelial face about 0.6 mm.; and the hole in the anterior lens-capsule about 1.5 mm.

The patient said he was 31 years of age when, as seems probable, the eye was injured in 1917. He stated that in 1917 he knocked his forehead on a piece of furniture at home and noticed next day that he could not see properly with his left eye. He went to his doctor who treated him in a general way for about

eight weeks. After that the patient sought ophthalmic advice and overheard the remark, made in discussion of his case, that "his lens must be dislocated but it was peculiar that it could not be seen anywhere." I mention this to emphasize how clear are his media by ordinary methods of examination. When I questioned him he recollected that some time before the incident of knocking his forehead, to which hitherto he had always attributed the impairment of vision in his left eye, he was chipping a piece of metal and felt a slight sudden prick in his eye. He thought his companion then removed a small foreign body. It would therefore seem clear that some eight years ago the patient sustained a penetrating injury by a very small object which, after passing through the cornea, perforated the pupil-margin and the anterior lens-capsule, but reached no deeper; in all probability a minute penetrating foreign body, having pricked the pupil-margin and the anterior lens-capsule, fell to the bottom of the anterior chamber there to lie behind the periphery of the lower part of the cornea. The blow on the forehead was incidental and served only to draw the patient's attention, for the first time, to the insidious dissolution of the lens-substance which had resulted from a previous small injury. It will be noted that the injury, though one of serious consequences, was from a mechanical point of view slight, ultimately leaving an eye which was devoid of all intracapsular lens-material but was otherwise practically normal. There is no adhesion and no pigmentary disturbance—for example, there is no vestige of pigmented or other deposit on the anterior lens-capsule—nor any abnormality of the corneal endothelium to suggest former inflammatory trouble. The visibility of the homogeneous beam of the aqueous fluid (examined according to the technique specified in "The Outstanding Beam of the Aqueous Fluid," *American Journal of Ophthalmology*, January, 1925) is normal. The case is probably unique in that not only has all intracapsular lens-material disappeared without any sign suggestive of past inflammatory trouble, but nowhere is there any proliferation of the capsular epithelium, nor is there any other change which would render these perfectly transparent thin capsules in any way abnormal save for the small hole in the anterior one.

The two thin capsules are reluctant and so the narrow slit-beam shows as two white stripes where it traverses them; thus slit-lamp examination reveals not only the presence of both capsules, but also their exact configuration. The capsules can be made tense and flat if the patient is told to look in the distance, or quite lax and distorted if he is told to look near. When a mydriatic is given the capsules become so tense and flat that, by slit-lamp observation methods, each is seen to be capable of acting as a plane mirror. The observations which I have recorded include the influence of various drugs on the state of tension of

the capsules and on the ability of the patient to render the capsules lax by a voluntary effort when the eye is subjected to the progressing cumulative influence of the drugs.

It should be explained how the slit-lamp effects were interpreted. When the slit-beam passes through a plane where the refractive index changes, for example from air to glass or from glass to air, a visible stripe is produced at the demarcation-face. If the face is flat the stripe is straight, no matter what may be the angle of incidence, to the face, of the illuminating beam or of the axis of observation. If the face is distorted the stripe is correspondingly distorted to an extent which is revealed with greater evidence the more obliquely inclined to the surface is the vertical plane of the ribbon-like slit-beam.

The contour and position of the lens-capsules of this patient are readily ascertained by study of the contour and the distance of separation of the two stripes produced by the accurately focused narrow slit-beam. When the capsules are tense and flat the stripes are parallel and straight (Fig. 2); and if now the eye is disposed so that the normal to the capsules bisects the angle embraced by the axes of illumination and observation each capsule, thus viewed by direct illumination along the axis of specular reflexion, may be seen to be so flat as to act as a plane mirror. As these capsules become lax the stripes are no longer straight, and with increasing laxity they become distorted and wrinkled so that, at all angles of observation, they show specular reflexes here and there off the summits or valleys of the component curves of individual wrinkles. In addition, with increasing laxity, the distance separating the capsules undergoes considerable increase.

Theoretically it is simple, by use of a micrometer ocular, to calculate the exact antero-posterior distance at any time between the two capsules, as being the ratio of the apparent distance to the sine of the angle embraced by the axes of illumination and observation; but sources of error tend to make this precise calculation unreliable and I omit it. Intermediately, when just short of being quite tense, the capsules are practically plane and though they show no wrinkles they may display fine vibration which, however, disappears when they become truly tense.

The ordinary state of these capsules—representing an average based on the results of many examinations in which the patient was given no special directions as to how or where he should direct his gaze—is as follows: They are usually slightly lax; the anterior is usually slightly convex forward; the posterior is usually a little wrinkled and more mobile. When wrinkled and lax the posterior is separated from the anterior capsule by a distance which varies. At times it will float forward displaying undulatory variations of its wrinkling so that it touches, especially in its centre, the anterior capsule (Fig. 3 (a)); at other times the distance separating the two capsules is greater (Fig. 3 (b)). Posture, as far as the apparatus permits of its variation, seems to have no influence on the laxity or disposition of the generally laxer posterior capsule—for example, its state does not seem to be influenced by a downward inclination of the patient's gaze.

When the patient is told to look in the distance the capsules straighten: they may not always go quite so straight and taut as they do when, in the manner described later, a mydriatic is given.

Sometimes, as the patient looks into the distance, the anterior capsule is very slightly curved forward and the posterior, not quite taut, lies close up behind it; at most times they both become quite straight and parallel (Fig. 2) as he looks into the distance. It should be added that these observations were made in a small dark-room and the patient's efforts at distant vision comprised no more than fixing his gaze on the faintly illuminated wall which was

FIG. 1.

FIG. 2.

FIG. 3.

not very far off; or else, with the room even darker, mentally concentrating his ideas on an unseen distance.

When he is told to look at a close object—for example, the microscope which he is facing—both capsules go noticeably lax, the posterior more than the anterior. The anterior may reveal no more than a few general wrinkles and some undulatory vibration; but the posterior undergoes marked relaxation, displaying not mere wrinkles but folds, so that it falls back like a slack sail lying edgewise to a wind, receding in its slackness from the anterior capsule (Fig. 4).

FIG. 4.

I do not know whether the separation of these capsules, when they are thus relaxed, signifies a transient negative pressure in the vitreous as the result of alteration of the volumetric capacity of the vitreous chamber brought about in some way by a change of shape of the ciliary muscle; on the other hand, it may be, as would seem more likely, that there is a free communication, through the fibre-gaps of the suspensory ligament, between the anterior vitreous fluid in the retrolental space and the fluid in the anterior chamber. As, however, the slit-lamp observations on this particular point which in the main are only a matter of surmise, I will not discuss it here but will confine this report to those observations whose results have led to definite conclusions. It may, however, be pointed out that the purposeless undulatory motions to which this posterior capsule is subject when it is very lax—as when under the influence of eserine—suggest that the fluid immediately behind it probably has no greater viscosity than that which is in front of it.

Tests repeated over and over again show that every time the region—for example, the lids—of the other eye is touched or pressure is made on the other eye, both anterior and posterior capsules of this affected eye at once go very lax—more lax than they become under the simple voluntary effort of looking near. I also found the same reaction on touching the lids of the affected eye under observation. I suggest that perhaps this indicates an automatic reaction of the accommodation mechanism which may be part of some general response to the primitive needs of protection in connexion with detecting the close and unexpected approach of objects. This very definite reaction tends to tire and become less marked, so that after the stimulation has been repeated twenty to forty times in close succession the response may cease, only to reappear after the patient has been given a period of rest. When this reaction is first tried, even the anterior capsule shows pronounced relaxation, bulging forward to an extent which, sometimes tending to approach that caused by eserine, reveals a much greater degree of relaxation than that caused by a simple voluntary effort of looking near. I ultimately found that such a pronounced reflex relaxation of these capsules could be brought about without any touching of the region of the eyes if the patient was told to make a conscious effort which, to use his own words, constituted "squeezing his eyes" without in any way closing his lids.

Hence we have an eye revealing that when the patient looks in the distance his lens-capsules go tense and flat and parallel. Then when he is told to look near both capsules relax, the anterior slightly, and the posterior moderately so that it displays kinks and folds and usually recedes from the anterior capsule. The relaxation is even greater if the other eyeball is pressed or if the patient makes a conscious effort at squeezing his eyes, when the capsules will relax much more—especially the posterior which will then show generous folds and will recede markedly from the anterior. Thus if the capsules are watched carefully from the moment of instillation of a mydriatic drug which is calculated to render them tense, as the drug begins to act a stage is soon reached at which the effort to look near fails to cause relaxation of the capsules, but, for a period, the stronger stimulus caused by pressure on the other eye, or by the patient making a conscious effort to "squeeze" the eyes, will successfully cause relaxation of the capsules. Presently, as the

instilled drug takes stronger effect, even this stimulus fails to influence the capsules which remain tense, flat, and parallel under all conditions. If now, when the capsules are tense under the influence of a weak mydriatic, a miotic is instilled a stage ensues in which temporary relaxation can be induced by the strong stimulus of pressure on the other eyeball but not, for the time being, by the patient being told to look near; and a little later, with deeper diffusion of the miotic, the tense capsules will momentarily become lax when the patient looks near but nevertheless will yet remain taut when the patient is not making this conscious effort; finally, with a still deeper diffusion of the drug, the capsules become quite lax regardless of any such stimuli and they then fail to respond in any way to efforts at distant gazing.

I will now quote from some records of the results of instilling drugs into the eye. For example, one evening at 9.20 some 2 per cent. cocaine was instilled. At 9.35—that is, fifteen minutes later—when the pupil was beginning to dilate, the posterior capsule was moderately straight; at 9.40 the posterior capsule was perfectly flat so that it could form a plane mirror, and the anterior capsule was similarly quite flat, the two being parallel and separated by a definite interval. At 9.50—that is, thirty minutes after the cocaine had been given—a drop of 1 per cent. watery solution of eserine was instilled. I did not re-examine the eye until four minutes later, by which time, though the pupil was still large and uninfluenced in size by the eserine, the capsules were markedly lax: the anterior was curved slightly forward, more especially in its centre, whilst the posterior was crumpled and very lax and was separated far from the anterior—much more than it would ordinarily be separated when not under the influence of the drug—so that when the anterior capsule stripe was in focus with the A2 objectives the posterior capsule stripe was very much out of focus. On re-examination at 10.5—that is, fifteen minutes after instillation of the eserine—the pupil was becoming quite small: close up behind it was the slightly convex non-tense anterior capsule, whilst seen far back—so far back that it was necessary to bring the illumination and observation axes to a close angle with one another—the posterior capsule, lax and wrinkled, could just be discerned.

On another occasion, when the capsules were normally lax, four drops of 2 per cent. cocaine were instilled at 10.1 p.m., after which the capsules were watched continuously. At 10.10 both capsules were straight, but when the patient looked near both became lax, especially the posterior. At 10.14 when the patient made an effort to look near, the anterior capsule did not relax perceptibly, but it vibrated a little, whilst the posterior relaxed. The pupil was just beginning to get larger than the other pupil. At 10.18 the anterior capsule was tense and plane and did not vibrate when the patient looked near; the posterior showed just a suspicion of relaxation when the patient made a strong effort to look near. As the pupil was now quite large, the axial region of the retina was flooded with the full beam from the fully opened slit so as to cause the pupil to contract well: the capsules remained uninfluenced in their tenseness, proving that the state of the capsular tension was independent of the size of the pupil. At 10.35 the effect of the cocaine had begun to wear off: when the patient was told to look near, the posterior capsule, but not the anterior, became markedly wrinkled.

On another occasion, at 9.24 p.m., two drops of 2 per cent. watery homatropine and cocaine were instilled. At 9.35 both capsules were flat and only the posterior became relaxed just slightly when the patient looked near. At 9.40 the pupil was larger. At 9.46 both capsules were straight, parallel, and tense, forming perfect plane mirrors when viewed in the axis of specular reflection. The strongest effort on the part of the patient to look near caused no relaxation of either capsule, nor was any relaxation caused by pressure on the other eyeball.

On another occasion homatropine and cocaine was instilled and an interval (thirty minutes) allowed to elapse until the pupil had become well dilated—so that a strong light-stimulus failed to cause any contraction—and the capsules had been rendered tense, so that all reflex efforts failed to elicit any sign of their relaxation. Then, at 10.29 p.m., one drop of 1 per cent. watery eserine was in-

stilled. At 10.31 a suspicion of tremor was evident in the posterior capsule and at 10.32 it was definite. At 10.32½ the capsular separation had increased slightly, and the posterior capsule showed slight wrinkling, whilst the pupil was still fully dilated and showed no sign of any tendency to contract when the fundus was flooded with light. At 10.34½ the posterior capsule was very lax and cockled, and the anterior was lax and showed a definite forward curvature, the two being widely separated (Fig. 5). At 10.38 the

FIG. 5.

dilated pupil just began to diminish in size; an effort of the patient to look near, or pressure on the other eye, did not at this stage influence the already evident laxity of the anterior capsule but it made the very lax posterior capsule apparently slightly laxer.

On another occasion, at 9 p.m., three drops of 2 per cent. atropine sulphate were instilled. A little over an hour was allowed for the pupil to become well dilated and the capsules to become straight and tense. Then (10.6 p.m.) two drops of 1 per cent. watery eserine were instilled. At 10.20 p.m. there was no evident effect on the tense capsules; another drop of eserine was instilled.

At 10.53 two more drops were instilled, up to which time the capsules had been

watched continuously; they remained tense, flat, and parallel, and neither efforts of the patient to look near, nor pressure on the other eyeball, caused the slightest relaxation. At 11 p.m. pressure on the other eyeball caused a slight momentary wrinkling of the posterior capsule. At 11.1½ the posterior capsule showed, spontaneously, slight cockling; the pupil was still fully dilated. At 11.30 the posterior capsule was more lax; the anterior capsule was still practically flat, but when it was seen in the axis of specular reflection, some slight contour variations appeared which indicated relaxing tension. The patient then went home; the pupil was still fully dilated; he stated afterwards that the pupil was still widely dilated next morning and that it did not become small until the evening—that is, twenty-four hours after the instillation of atropine followed an hour afterwards by eserine.

On another occasion, at 8.45 p.m., and with repetition afterwards, a small quantity, in powdered form, of the sympathomimetic drug p-hydroxyphenylethylamine (tyramine) was placed in the conjunctival sac. It caused dilatation of the pupil, but did not produce any evident influence on the capsular tension. Following this, at 9.19 to 9.21, about twelve drops of 2 per cent. cocaine were instilled. At 9.25 to 9.27 the capsules showed the usual state of tension resulting from the instillation of cocaine, and by that time a strong effort on the part of the patient to "squeeze" the eyes and also to look near caused only a very slight cockling of the posterior capsule, this reaction being practically abolished by 9.33. At 9.35 1/30 grain of solid homatropine hydrobromide was placed in the conjunctival sac. At 9.47 two drops of 1 per cent. eserine sulphate were instilled, at which time no efforts to cause reflex relaxation of the very tense capsules produced any effect. At 9.49 the capsules were still tense, even when the patient made a strong effort to "squeeze," and another drop of eserine was instilled. At 9.50 the effort to "squeeze" produced ample cockling of the posterior capsule; at 9.51 both capsules remained, spontaneously, quite lax and widely separated, the anterior being, especially in its centre, markedly concave forwards and the posterior thrown into generous folds, the laxity of both being increased when the patient made an effort to "squeeze." At 9.52 to 9.52½, but not before, the pupil just began to show signs of contracting, but it did not become small rapidly: at 9.58 it was still rather large, while both capsules had become so lax that they trembled and waved freely with every movement of the eye, even when the patient merely blinked. At 10.2 the size of the pupil was approaching that of the other eye.

On another occasion, from 9.45 p.m. onward, three to four instillations of 2 per cent. cocaine were given over a period of five minutes, and by 10.3 both capsules were

fully tense. At 10.7 two drops of 1 per cent. pilocarpine were instilled. At 10.10 the capsules were still tense and the pupil was still large. At 10.15 the pupil was still large, but it just reacted faintly to light when the patient looked up at a lamp on the ceiling, though no trial had been made to see if the pupil reacted thus immediately before the instillation of the pilocarpine. At 10.23 the pupil showed signs of reacting readily to light. The capsules were both straight, but would now become lax when the patient looked near, the posterior showing bends and waving well back and the anterior revealing a suspicion of forward convexity. At 10.25 the pupil was smaller than the other pupil, even in a dim room-light. At 10.26, when the patient looked in the distance, the anterior capsule became tight but the more lax posterior capsule failed to tighten and remained lax; if the patient looked near the anterior capsule became, especially in its middle, moderately convex forwards, whilst the existing laxity of the posterior capsule was increased. At 10.33, when the patient looked in the distance, the capsules became about as they would be when, at 10.26, he looked near; but now, when he looked near, the anterior became definitely convex forward and the posterior became so lax that, separated far from the anterior, it was not merely wrinkled but became folded and buckled with gross angular kinks. At 10.35 the capsules remained thus no matter whether the patient was looking near or in the distance. This was the only occasion on which I tried the use of pilocarpine.

On another occasion novocain dilated the pupil a little but produced no evident effect on the state of tension of the capsules.

On another occasion adrenaline neither dilated the pupil nor affected the capsules.

These particulars which I have quoted now, abstracted from extensive notes, are a record of observations which I have been careful to ensure are devoid of errors. It might be that a full report on all the observations of this case would be of interest to others besides ophthalmologists—for example, physiologists and pharmacologists. If at any time they are desired, I should be glad to provide a fuller account of the observations made: they are too extensive to submit in full in this communication.

In general, I may summarize in conclusion that the behaviour of these capsules shows that one mechanical result in the process of accommodation consists in a relaxation of their state of tension. Further, if a mydriatic is given the capsules are rendered taut; and if time is allowed for these capsules to get just so taut that they do not relax when the patient gazes close, but not so taut that they fail to relax when the other eye is pressed, and the fundus is at this stage flooded with a sufficiently strong light-stimulus to cause good contraction of the already moderately dilated pupil, the pupil-contraction thus produced takes place without causing any evident relaxation of the existing capsular tension, showing that tension of these capsules caused by the mydriatic is independent of the dilatation of the pupil which is also caused by the mydriatic. If, when the pupil is well dilated and the capsules are tense under the full influence of a mydriatic and cycloplegic such as cocaine or homatropine, eserine is then instilled, in a very short time the capsules begin to relax and they then rapidly become extremely lax—far more lax than they ever were without the influence of a drug such as eserine—this occurring before contraction begins in the pupil which is still fully dilated by the mydriatic. When a stronger drug such as atropine is used, though longer time is required for the eserine action to begin to show itself by reduction of the capsular tension, even so this result occurs before the miotic begins to show its influence in diminishing the size of the dilated pupil. Tests made on other occasions which I have not quoted here confirmed that eserine acts on the capsular tension before it begins to act on the size of the pupil, when this eye has previously been subjected to the influence of a mydriatic.

The very definite slit-lamp observations on this unique eye, both as to the response of the capsules in the act of accommodation and as to the influence of drugs upon this response and upon the capsular tension in general, may

justifiably be accepted as affording satisfactory and conclusive evidence of the principle of the alteration of the state of tension on the normal lens-capsules in the act of accommodation, and of the influence which the various drugs experimented with may normally have upon this tension.

PHYSIOTHERAPY IN THE TREATMENT OF ARTHRITIS.

BY

R. G. GORDON, M.D., M.R.C.P.ED.,

PHYSICIAN TO THE ROYAL MINERAL WATER HOSPITAL, BATH; MEDICAL
OFFICER IN CHARGE OF THE PHYSIOTHERAPY DEPARTMENT,
ROYAL UNITED HOSPITAL, BATH.

For the purpose of the present article it is proposed to limit the field of discussion to acute and chronic infective arthritis of non-tuberculous origin, climacteric arthritis of metabolic origin, periarticular fibrositis and bursitis, and osteo-arthritis. The forms of physiotherapy to be discussed are massage, active and passive movements, stimulation by the faradic and galvanic current or the Bristow coil, radiant heat, ionization, and diathermy. Hydrotherapy, in all its forms, is deliberately omitted, as it forms a separate study, and the numerous other forms of electrical and mechanical appliances are not referred to because it is very doubtful if anything can be effected by them which cannot be done by the simpler methods enumerated above. Moreover, with the possible exception of radiant heat and diathermy, these are usually within the reach of any practitioner even in country districts; but heat can, in fact, be applied by methods other than radiant heat, and ionization will serve much the same purpose as diathermy, if the latter is not procurable. Those skilled in massage and physiotherapy are available almost everywhere, and portable faradic and galvanic batteries are relatively inexpensive. Ionization can be given adequately with the latter, provided a milliamperemeter is attached.

Acute Infective Arthritis.

In this condition the joint is exquisitely tender and swollen and the skin over it is hot and red. If the condition is prolonged the muscles round the joint waste rapidly, and this, coupled with the swelling and consequent stretching of the ligaments, may ultimately result in a lack of stability of the joint. This causes a serious disability later, when the patient should be able to resume an active life.

The first indication for treatment in this form of arthritis is to keep the joint at rest until the inflammation has subsided. As there is a possibility that an acutely inflamed joint may become fixed, it is important that it should be kept at rest in the optimum orthopaedic position. Thus, in the event of this unfavourable result a maximum of useful movement can be obtained through the shoulder girdle and pelvis in the case of the proximal joints, and requisite stability for weight-bearing in the case of the knee, while the other joints are in such a position that the important functions of the limb are still possible. In this country splints and plaster which completely immobilize the limb are the usual methods employed, but in view of the results obtained by Professor Rollier in his clinics at Leysin, and by others, it is by no means certain that it would not be better, where possible, to restrain the joints by means of sandbags or plaster troughs. These enable the patient to make small voluntary movements, and it is noticeable that voluntary movements never do harm to a joint, for the pain resulting from the threat of too great movement immediately inhibits the movement. The result of these small harmless active movements is that there is extraordinarily little muscular wasting, even although, as is the case at Leysin, no massage or other form of physiotherapy is used.

The second aim is to restore and maintain the tone of the surrounding muscles so that the ultimate stability of the joint is endangered as little as possible, and the patient

is enabled to resume active life at the earliest possible moment. This can only be achieved by exercising the muscles without disturbing the joint, either by allowing small active movements as described above, or by careful massage. Splints, if used, should be so fashioned that they can be removed sufficiently for the masseuse to get at the muscles without disturbing the position of the joint. The massage must be strictly confined to the bellies of the muscles, and care should be taken not to cause any pull on the ligaments which form the capsule of the inflamed joint. For this reason any effort to restore muscles by electrical stimulation is contraindicated, since the resulting muscular contractures inevitably disturb the periarticular structures. In no circumstances should the joint itself be touched by the masseuse, even if the position is bad, for sudden movements will only intensify inflammatory reactions, and changes in posture are better effected by the steady and gradual traction of properly applied extension apparatus.

The reduction of inflammation and swelling can be effected by counter-irritants such as Scott's dressing or blisters or by ionization. The latter process consists in the application of pads of lint soaked in certain saline solutions to which are attached electrodes in the circuit of a galvanic battery. In this way a constant current is passed through the joint, and the burning of the skin which would result from the direct contact of the zinc electrodes is prevented by the pads. The original theory of this method of treatment was that certain drugs were conveyed into the joint in an ionic and therefore extremely active form. There is considerable evidence to support the contention that the metallic and acid radicles are carried into, and possibly through, the skin and distributed by the blood stream, but it is extremely doubtful if the drugs reach the deeper tissues of the joint. The action of ionization would appear to be twofold: in the first place, the skin is stimulated and the effect of counter-irritation is produced; and secondly, the passage of the current through the joint results in a local hyperaemia which ensures the neutralization of toxins and the removal of waste products. Ionization should be applied for twenty minutes on alternate days with a current of from 30 to 70 milliamperes, varying with the tolerance of the patient, till the swelling and redness have reached the limit of subsidence. This method should not be applied over broken skin, and any complaint of too severe pricking or irregularity in the register of the milliamperemeter independent of the supply of current are warnings that burning may occur and indications to reduce the current.

Subacute and Chronic Infective Arthritis.

In this condition the joint is no longer hot and red but may still be swollen and tender. In many cases, as they are brought to the physician, deformities of the joints have already occurred, whether from the spasm of neighbouring muscles or the formation of adhesions, and these deformities require to be corrected. In practically every case marked muscular wasting is present and there is considerable trophic deterioration of the skin, which becomes shiny, blue, and cold. Treatment should be directed to the correction of deformities, removal of swelling, and restoration of muscular tone. In the correction of deformities the question of an anaesthetic is of some importance. For diagnostic purposes this is of great use. Under an anaesthetic all muscular spasm is relaxed, so that the extent of the deformity due to adhesions may be estimated. Corrective plasters may be put on with advantage when the muscles are relaxed, but this should be the only form of treatment practised under anaesthesia. The temptation to break down adhesions is considerable, but should never be yielded to in any circumstances. Admittedly brilliant results are sometimes obtained, but the risks are too great. If the adhesions are extra-articular they can be broken down by active and passive movements, as will presently be described, but if intra-articular, they can only with difficulty be stretched or broken down at all, and the attempt to do so suddenly, without the restraint of the subjective feelings of the patient, leads inevitably to fresh haemorrhage into the joint, with subsequent formation of still more dense adhesions. Where adhesions occur, therefore, it is better to exercise

patience and trust to active and passive movements. Where the condition of the joint is still subacute and thus liable to flare up into active inflammation it is best to trust to active movements by restoring the muscles by massage and encouraging the patient to stretch his joints himself. If he is prepared to work really hard in this way the desired result will be obtained, with the safeguard that the reflex inhibition of movement will prevent him doing any harm. In any case, increased heat, redness, or swelling in the joint is indicative of too much movement and the necessity for rest.

Before any effort is made to correct deformity, whether by active or passive movements, it is well to relax the muscles concerned by radiant heat or diathermy. The former exposes the part to a dry atmosphere which can be raised to a considerable temperature without burning—300° to 400° F. The latter is a process whereby the heat and blood supply of the joint are increased by the passage of an interrupted current by a method similar to that used in ionization. It is often found after these treatments that with the relaxation of the muscles there is a considerable reduction in the pain of the joint, and the patient may get up and think some miraculous cure has been achieved. Within a very few minutes, however, the spasm and the pain usually return. The reason for this is that the muscular spasm is Nature's method of splinting so as to prevent contact of painful and inflamed surfaces, and although this special contact may be avoided for some moments in certain postures, sooner or later a position is adopted which does involve the painful contact, and spasm returns. For this reason, when it is desired to correct deformities by movements after muscular relaxation and these deformities are pronounced, it may be necessary to preserve the correction obtained by plaster or other splints. These may be removed after a day or two and the joint further relaxed and the splint reapplied. While a joint is so inflamed as to induce repeated muscular spasm whenever a particular contact occurs, much mobilization should not be expected or attempted, and the aim of treatment should be to attain the optimum orthopaedic position. Joints may, however, remain stiff, either from adhesions or muscular spasm, after all active inflammation has subsided; in the case of adhesions these may be gradually stretched as described above. Where muscular spasm persists this is due to the persistent suggestion induced by the previously painful and inflamed joint. In such cases efforts should be made to induce the patient to relax the muscle and persuade him that the spasm is unlikely to recur. The old posture of the limb, however, may be maintained for some days until use has restored the normal postural tone of the muscle.

Reduction of the swelling in the joint may be furthered by increasing the vascular supply by radiant heat or diathermy, or by ionization used in the way described above. In all such treatments, however, great care must be taken not to burn the skin, which is usually unhealthy. Too prolonged or too intense applications are dangerous, and it is better not to give the treatment more often than once on alternate days and gradually to work the current up to the requisite strength. If the pads used for diathermy and ionization are not evenly soaked in the saline solution, sparking and short-circuiting are apt to occur and much increase the risk of burning. As is well known, electric burns take a very long time to heal and may interfere with treatment of the joint just when steady persistence is of the utmost importance.

The restoration of tone in the muscles is effected by massage, as is done in the acute joint, but when active inflammation has subsided this may be more vigorous and may be supplemented by electrical stimulation of the muscle, whether by interrupted galvanism, faradism, or the Bristow coil. These will all tend to restore both tone in the muscles and better circulation in the skin, with a more rapid return to normal.

Climacteric Arthritis.

This arthritis commonly met with in women at the menopause is closely allied to the chronic villous arthritis in which the swelling of the joint is chiefly due to an overgrowth of synovial membrane. This arthritis is often associated with infective foci, but the general metabolic change

in the body is more obvious and important than these. In the common type mostly affecting the knees of middle-aged women there are signs of definite thyroid deficiency, and thyroid extract should always be tried. The joint is swollen and puffy, the bursae being concerned in the synovial as the joint surfaces themselves. As a result the joint is often shapeless and unstable from the stretching of the capsule. Coarse grating on movement, due to the dried synovial fringes riding over each other, is common. The joint is stiff, painful, and moderately tender, but not as a rule red or hot; the surrounding muscles are wasted, but not more than would be expected from the disuse of the limb, in contradistinction to the marked atrophy of acute infective arthritis. The wasting is somewhat masked by the general myxoedematous condition of the skin and subcutaneous tissues.

The condition being one of deficient circulation in the joints, the chief aim of treatment is to promote the blood supply to the part. Radiant heat, diathermy, and ionization are useful here, especially the last two. Massage is necessary to restore muscular tone, and in these joints a certain amount of friction to the joint assists in the supply of blood to the part. Movements, both active and passive, are used to restore mobility, and these can be practised relatively freely as there is less risk of setting up an acute inflammatory attack. Most of the patients with this type of arthritis are too heavy, and since the incidence of the disease is usually in the knees and ankles this is an important factor in the case. There can be no doubt that once the synovial membrane has taken on the habit of proliferation, the continued close approximation of joint surfaces when a heavy person walks tends to increase this synovial overgrowth. Measures directed to reduce weight are therefore important; they comprise the administration of thyroid extract, dietary measures, and general massage, in addition to local treatment. At the same time, in the more severe cases it may be desirable to take the weight of the body off the affected joint for a time. As it is essential for the general health and reduction of weight that the patient should get about, the only method available is by fitting some form of walking calliper modified according to the joint affected; the general principle is to transmit the body weight from the pelvis by means of steel bars to the heel of the boot below the ankle-joint.

Periarticular Fibrositis.

This is a special variety of a generalized fibrositis affecting the fibrous capsule of the joints. The characteristic lesion of fibrositis is the replacement of inflamed fibrous tissue by scar tissue, which is liable to contract. This contracture leads to thickenings which, if still the seat of inflammation, are tender and form nodules, and to shortening of the ligaments, which, if allowed to persist, pull on the ends of the opposing bones and results in deformities.

In periarticular fibrositis there is no definite swelling of the joint, and the wasting of the surrounding muscles is that of disuse rather than of trophic disturbances. Tenderness may be considerable, but is generally localized to affected areas in the ligaments and not to synovial surfaces. There may be much pain on movement and restriction of mobility. In the ball-and-socket joints—the hip and shoulder—rotary movements (which are specially restricted in a true arthritis) are relatively less restricted than flexion and extension, abduction and adduction.

The aims of treatment are reduction of active inflammation, restoration of mobility, and removal of scar tissue. The first object may be attained by radiant heat, diathermy, or ionization, and, on the whole, experience shows that local radiant heat gives the best results. When the pain and tenderness are lessened treatment should be directed as soon as possible to the two last objects, as once the contracture of the scar tissue has induced much stiffness and deformity the restoration of full function is difficult. Massage should be employed, as in other forms of arthritis, to restore muscular tone and efficiency, so that the patient may use his own efforts to recover movement of the joint. In addition, the localized thickenings in the ligaments must be sought for by careful palpation, taking care not to mistake small inflamed bursae for these; when found they must

be subjected to deep kneading, with the object of softening and stretching the scar tissue and, if possible, getting rid of it altogether. The patient must be warned that this process will be painful, but at the same time encouraged to expect the benefit which results from successful treatment. Massage must be supplemented by active and passive movements, persistent but never sudden, the degree of stretching the adhesions at any one time being guided by the patient's feeling of pain. As has been said above, it is better to progress slowly than risk any actual tearing of these fibrous bands, which may give rise to bleeding and subsequent formation of fresh adhesions. By these methods deformities may be reduced, and scar tissue dispersed at the same time.

Periarticular bursitis is common in the neighbourhood of all joints, and is characterized by tense swollen bursa which may be hot and red. These are tender to palpation and painful when the joint is moved in such a way as to stretch or press on the inflamed synovial walls. The condition is apparently due to the infection settling in a bursa irritated by a constant strain on the surrounding tendons and ligaments. This is well illustrated by the clinical picture of subacromial bursitis as described by Buckley. With the arm at rest by the side there is a point of extreme tenderness if the bursa is palpated under the tip of the acromion. As the arm is abducted there is severe pain while the wall is stretched by the action of the supraspinatus whose tendon crosses the floor of the bursa. With abduction beyond a right angle, however, both pain and tenderness disappear as the bursa passes in below the protecting acromial process. As these conditions are due to strain or trauma in conjunction with infection, the joint must be protected from the strain or trauma, whether the swing of a golf-club, the use of a tennis-racket, or other such movement, until the inflammation has subsided. For hastening this end, ionization is the method of choice; it combines counter-irritation with the direct increased blood supply to the part from the passage of the current. Once the inflammation in the bursa has subsided there is no difficulty in restoring mobility and full function.

Osteo-arthritis.

In this condition rarefaction and absorption of the bone occurs with compensatory formation of osteophytes and overgrowths. The joint surfaces become eroded, and with the destruction of the synovial linings the sensitive cartilaginous surfaces come into contact with each other, causing intense pain and inducing protective muscular spasms. These spasms may result in considerable deformities, and the formation of osteophytes may take place in such a way that restoration of the opposing bones to their normal alignment is impossible. Cases which have progressed to this stage cannot be helped to any great extent by physiotherapy, and indeed any treatment short of active surgical intervention to immobilize the painful joint gives little promise. Moreover, since the condition is most frequently met with in old debilitated persons, little able to stand a major operation, even this method is not often applicable. Every effort should therefore be made to arrest the condition in the early stages, or prevent deformity of joints. Since strain and pressure favour the formation of osteophytes, as soon as the joint can be got into the best orthopaedic position by extension apparatus, weight-bearing splints must be applied to prevent the direct apposition of joint surfaces and convey the stress of the body weight past the affected joint. In order to achieve the object of relieving muscular spasm and restoring good position and at all times to relieve pain, radiant heat is of the greatest service. Massage to muscles is of use in maintaining tone, but care must be exercised that the hypertonia existing in those muscles already in spasm is not increased by injudicious treatment.

I do not suggest for a moment that other methods of treatment of the various forms of arthritis referred to in this paper are not of the greatest use, and in some cases almost essential; but it is useful to indicate that much may be done for these troublesome and all too common afflictions by methods that are within the scope of the available therapeutic armamentarium of most practitioners and within reach of the pockets of most patients.

END-RESULTS OF ARTIFICIAL PNEUMOTHORAX.*

BY

S. VERE PEARSON, M.D., M.R.C.P.,
PHYSICIAN, MUNDESLY SANATORIUM.

THE following results are based upon a series of 78 patients whose treatment was commenced fifteen to three years ago. Of those who recovered, only 4 were started later than December, 1921, and only one later than June, 1922. All the patients were in the third stage of pulmonary tuberculosis and were sputum-positive. They were patients who had failed or who were failing to respond to the ordinary sanatorium régime.

Table Summarizing Results.

	Operation Practicable.	Operation not Practicable.
Able to work:	29+4=42.3 per cent.	2
Dead	31+5=50.0 "	9 (6+3)
Dead from other cause	1	—
Ill with tuberculosis	3	—
Lost sight of	2	3
Total	69+9	11

The 9 patients put separately were some who were largely under my care during the period mentioned, but artificial pneumothorax was not started originally at the Mundesley Sanatorium. During the same period there were 17 patients in whom only a partial pneumothorax could be produced; 8 of these are dead, 4 are well and working, 1 is ill, and 4 I have lost sight of.

Of the patients who died, one lived twelve years, another seven and a half years, both enjoying good health for the greater part of these periods. Others lived six, five, five, and four years respectively; others, again, lived only a few weeks or months. The average duration of life of the 47 patients who died (including the cases of partial pneumothorax) was two and one-third years; and the duration is the same if only the 34 of the first group are taken into account. By comparing this duration to the duration of life of sputum-positive cases of all types treated by other means than artificial pneumothorax (as illustrated, for example, in Dr. James Watt's article in *Tubercle*, August, 1924), it can be seen that life was prolonged appreciably by means of this treatment, even in the cases who eventually died of tuberculosis. From a study of the above statistics it can be said that in any case of moderately advanced pulmonary tuberculosis which is fairly unilateral, the prognosis is best if compression treatment be undertaken and if feasible.

The comparison in the table also makes clear that artificial pneumothorax is successful when the results are compared with similar cases for whom this treatment has not been possible on account of generally adherent pleura. It will be seen from the table that the death rate with these patients is much heavier. Yet the conditions which lead to the choice of a trial of compression were the same in both cases. No one can say beforehand which patients have good adhesions.

I always advise maintaining the pneumothorax for at least three years. Often four, four and a half, or five years are found advisable. But this is not a hardship, for, ere the day of the refill, the patient's workaday life need be seriously interfered with. The average duration of period of refills in those of my patients (34) who recovered is four years and four months; and the average duration of life since commencing treatment is six years and ten months.

The question of how far the recovery goes, how far working capacity is restored, is of interest. To what extent does the lung re-expand after the treatment has stopped? Since the patients dealt with in this series

* Summary of a paper read before the Assurance Medical Society, November 4th, 1925.

third stage, sputum-positive cases not progressing well under the ordinary régime, restoration to a quite full working capacity cannot be expected in all cases, or in the first few years. Occasionally patients soon make a complete recovery. This is especially likely to occur in young persons with sound contralateral lungs. The expectoration of sputum containing tubercle bacilli is usually an early symptom to cease.

The extent of re-expansion of the compressed lung varies, and cannot easily be predicted. In rather more than one-third the re-expansion is fairly complete. The scarring in the lung shows chiefly through cardiac, and, if on the left side, stomach displacement. The heart is pulled over to the affected side. There are no adventitious sounds, but the breath sounds may remain permanently a little weak. When much destruction with excavation of the lung has taken place, a considerable opening up of the lung is usually neither desirable nor often found.

Other figures giving the end-results of pneumothorax treatment can be found in a recent paper by Dr. R. C. Matson and others in *Tubercle* for October, 1925, and in Dr. Gravesen's *Surgical Treatment of Pulmonary Tuberculosis*, 1925, Table I (p. 52). These statistics show from 30 to 40 per cent. of cures.

THE NATURE AND USES OF REFRACTOMETRIC AND VISCOSIMETRIC TESTS.

BY

CHARLES A. H. FRANKLIN, M.D., B.S.,
M.R.C.S., L.R.C.P.

During the last twenty-five years a great amount of work has been done on viscosity of the blood and serum, most of it since the introduction in 1906 of Hess's viscosimeter. In clinical work, it is the *relative viscosity* which is measured (of blood, serum, oedema fluid, etc.), compared with distilled water. Refractometry gives us the protein content of serum, oedema fluid, etc.—that is, the degree of concentration of the protein.

Viscosity plays an important part in the circulation. That the blood pressure itself is dependent upon the state of the heart and the vessel walls has long been recognized, but it is only recently that the part played by viscosity has received attention, and its importance in pathological conditions has been realized. Allbutt recognized this in his review in 1911,¹ the viscosity of the blood increasing the heart working many times, compared with what it would be if it were water.

Viscosity is a property of the blood, and is subject to variations, slight daily, marked in pathological conditions. The blood carries cells in suspension, salts in solution, and a viscous protein. Viscosimetry and refractometry help to throw light upon the changes in the tissues and the alterations in the water content of the blood in varying conditions.

Viscosity in relation to work becomes an important factor in circulatory and cardiac disturbances. A blood examination cannot be considered complete without a viscosimetric-refractometric examination being undertaken. The value of determining the viscosity has been well summarized by Bircher,² as threefold:

1. In circulatory questions, viscosity should be considered. Red cells and viscosity are the two opposite factors which have a determining influence on the effect of heart work.
2. The viscosimetric factor is an excellent check of the normal blood test, because it depends on the different constituents of the blood. It is a delicate indicator for changes in their relation, and on this fact is based some valuable diagnostic information.
3. The viscosity is an accurate means of analysing the constituents of the blood; the quantity and quality of protein in

plasma may be studied as well as the exact volume of the cellular elements. On these determinations are based the diagnostic applications supported by Naegeli.³

Instruments.

The viscosimeter of W. R. Hess of Zürich is used, which is not only very simple and reliable, but the only one which fulfils all the necessary conditions; it is based on the law of Poiseuille, according to which fluids at equal temperature and pressure, passing through capillary tubes of equal calibre, vary in their rate of flow in direct proportion to their internal friction—that is, to their viscosity. The clinical model shown in the diagram is the most generally useful, being compact and portable.

Method.

Only one drop of blood is required, obtained from a stab in the finger after immersing the hand in a basin of warm water for two to three minutes. The blood is collected in a short length of narrow glass tubing, E, specially supplied, which is at once brought into opposition with the end of the blood capillary tube K₂; the tube E is held in position by being pressed into a spring clip F. By means of a bulb the blood is immediately sucked up to the 0 mark. The tap H is now opened and both water and blood columns are drawn along until the blood in tube K₂ reaches the 1 mark. After reading the point reached by the column of water the blood is expelled, and the tap is turned off as soon as the water has been driven back to zero. The blood tube, K₂, is at once cleaned by sucking in and expelling ammonia, water, alcohol, and ether in succession. Although the method is not by any means free from errors, it is sufficiently accurate for clinical purposes.

Blood is then collected in a U-tube, each limb 4 inches long, no pressure being made on the finger; this is centrifuged, and when the supernatant serum is clear one limb is cut off just above the blood clot and the viscosity of the serum is measured, the other being retained for refractometric examination. (A full description of the viscosimeter is given in Bircher's review,⁴ and of the refractometer in the booklet supplied by the makers.) The refractometer of Pulfrich (Zeiss's dipping refractometer) is used, which gives the angle of refraction of the fluid; this reading is converted into grams of protein per cent. by means of E. Reiss's table.

The viscosity of the blood depends upon:

1. The mass (whole volume) of the cells. An increase raises the viscosity, and a fall in number lowers it, but the viscosity is not directly proportional. (Du Pré Denning and Watson,¹⁴ Münzer,¹⁵ Bence.⁵)
2. The haemoglobin content. (Lisbonne and Margat.¹⁶)
3. The number of

the white cells per cubic millimetre. The viscosity is increased in leukaemia, the white cells conducting more, in proportion, to the viscosity than do the reds. (Determann,¹³ Rotky.²²)

4. The carbon dioxide content. The viscosity is raised in cyanosis; venous blood is more viscous than arterial, and oxidation lowers viscosity. (Koranyi and Bence,⁶ Adam,³ Determann,¹² Austrian.⁴)

5. The protein content. Dehydration increases the viscosity, and hydraemia lowers the viscosity. After a severe haemorrhage by the rectum I have observed it to fall from 4.0 to 1.75. (Nicastro-Ferro,¹⁹ Lommel.¹⁷)

6. The salt and urea contents—of small influence. (Bottazzi.¹¹)

The average viscosity of the whole blood may be taken as 4.5 to 5.3 in men, 3.9 to 4.9 in women, and of serum as 1.7 to 2.0 in both (Naegeli). The viscosity of the serum depends chiefly upon the protein content.

Considerations of space make it impossible to enter into

The essential part of the apparatus consists of two capillary tubes, K₁, K₂, connected to a single aspirator S, Gb; by the aid of a strong rubber bulb, Gb, distilled water and blood (or serum) are simultaneously drawn through the two capillary tubes K₁, K₂, respectively. If the blood is sucked up tube K₁ from 0 to 1 the column of water reaches a point in the graduated tube K₂, which indicates directly how much further the water has flown in the same time and under the same conditions. The reading is then taken at the point which the water has reached, say 4.3; this reading is the viscosity of the blood. No correction need be made for temperature between 17° and 23°C.

DELIVERY OF BREECH WITH EXTENDED LEGS.

BY

NORMAN B. HALL, M.B., B.S.ADELAIDE,

AND

HILDA W. PAGE, M.R.C.S., L.R.C.P.,

LATE SENIOR MEDICAL OFFICERS AT QUEEN CHARLOTTE'S MATERNITY HOSPITAL.

With the object of discovering the most satisfactory method of treating a breech presentation with extended legs, we have recently investigated the details of 100 cases that have occurred at Queen Charlotte's Maternity Hospital during the last ten years.

Of the 100 cases only 6 were delivered spontaneously with legs extended; with the remainder the legs were brought down before delivery. The average weight of the children born with extended legs was 5 lb. 10 oz.; when the legs were brought down the average weight was 7 lb. 7 oz. The delay was so considerable that it practically amounted to obstruction in 47 of the cases where the legs had ultimately to be brought down; that is to say, the breech did not advance in spite of good pains, although left as long as two hours in the second stage. Of these 47 cases, 28 were delayed in the cavity of the pelvis and 19 on the perineum; in the latter condition the difficulty in pulling down the legs was much greater.

Of the remaining 47 cases no record was kept of the reason for the bringing down of the legs, but in all the breech was well down in the pelvic cavity or on the perineum before the legs were brought down. The inference is that in the majority of these cases there was some delay at the outlet. In most cases both legs were brought down simultaneously. When only one leg was brought down it was generally necessary to bring down the other at a later stage.

After the extended legs had been brought down the presenting part advanced regularly without further interference. Sometimes this advance was found to be slow, but it was not accompanied by foetal distress. When the child was born as far as the umbilicus the position of the arms was then ascertained. They were found to be extended in 84 cases, 6 of these being instances in which delivery took place spontaneously with legs extended. In the remaining 88 cases the legs had merely been brought down and not

pulled on, nor was fundal pressure used until the arms had been brought down. This, in our opinion, is of great interest, as it appears to show very clearly that the extension of the arms is a primary condition, and not, as generally supposed, the result of the legs being pulled on. In every case the arms were pulled down and the head delivered without delay by various methods (the Prague, Mauriceau-Veit combined with fundal pressure). In 13 cases great difficulty was encountered in the delivery of the head. Apparently this was due in the majority to extension of the head. In 2 cases forceps, applied to the after-coming head, were used with success, and in 4 perforation through the roof of the mouth was necessary before delivery was possible.

Conclusions.

The conclusions we have drawn from the investigations and from our personal experience of 20 cases are as follows:

1. As a general rule extended legs have to be brought down.
2. In the comparatively few cases where it is not absolutely necessary, it will shorten the labour and lessen the sufferings of the patient if the legs are brought down.
3. The right time for bringing down the legs is as soon as the os is fully dilated. It must be understood that each case must be treated according to the attendant circumstances.
4. When the presenting part is not advancing we consider that the legs should be brought down although the os may not be fully dilated. In these circumstances the os should not be rigid, and it should be at least three-quarters dilated.
5. It was noted that there was greater difficulty in bringing down the legs when the delay was on the perineum.
6. Before the legs are brought down an anaesthetic must be administered. The result is that temporarily the pains either cease or become weaker. In our opinion it is better to bring down the legs and then wait until the pains become stronger, when the patient will be able to deliver the child as far as the umbilicus. No harm will be caused to the child by this delay. Unless there is a definite indication such as foetal or maternal embarrassment, we consider better both for mother and child not to pull on the legs all after they have been brought down.
7. When the child is born as far as the umbilicus a loop of cord can be pulled down and watched. The position of the arms must then be ascertained. If found to be extended (this is usually the case) they must be brought down. Before doing so an anaesthetic must generally be administered. The posterior arm must be found and pulled down, then the anterior. If there be any difficulty the body should be rotated so that the anterior arm becomes posterior. This will give more space by reason of the hollow of the sacrum, and the bringing down will be accomplished with greater ease. At this juncture, and not earlier, the skilled assistant can follow the head from above and endeavour to keep it flexed.
8. As in most cases there are difficulties with the after-coming head, we consider that it is best to use the Mauriceau-Veit method, with fundal pressure from above. In combination with this method and in those cases where the head is not well flexed, it has been found advantageous first to push up the occiput with the fingers of the right hand, thus helping to flex the head, then to get two fingers of the left hand well down over the tongue, not only just inside the mouth. When this has been done both hands should pull in the axis of the pelvic outlet, and fundal pressure should be applied in the same axis. The pushing up of the occiput and the placing of the fingers well inside the mouth instead of just inside the lower jaw are two points which we consider of much importance.

Summary.

- We are of the opinion that care should be taken—
- (a) In deciding the propitious time for bringing down the legs.
 - (b) In realizing the importance of not pulling on the legs when once they have been brought down.

(c) In ascertaining the position of the arms in the uterus as soon as the child is born as far as the umbilicus.

(d) In the delivery of the after-coming head, with special reference to the pushing up of the occiput and placing the fingers well inside the mouth of the child before delivery.

We wish to express our deep obligation to the Committee of Queen Charlotte's Hospital for the use of the above statistics, and our sincere thanks to Mr. Aleck Bourne for his generous help and advice in preparing this paper.

LUMBAR RIB OF UNRECORDED TYPE.

BY

JOHN CUMMING, M.B., C.M.GLAS.,
CHIEF POLICE SURGEON, HULL CITY POLICE.

On September 26th, 1925, a member of the city fire brigade attended sick parade and stated that on the day previous, whilst practising with a jumping sheet, he had injured his back. He also stated that on November 25th, 1922, he had fallen into one of the dry docks in the city and had injured the same place as well as his left upper arm.

He was seen at that time by my predecessor, Dr. J. Wright Mason, who ordered his left arm to be x-rayed, for the reason that he complained more of the injury to this than to that of his back. The x-ray photograph showed nothing abnormal, and after a lapse of a few weeks he returned to full duty.

On examination I found that he had a very tender point corresponding to the transverse process of the fourth lumbar vertebra, but both Dr. David Hyslop, my assistant, and I were of the opinion that he had ruptured some of the muscular fibres of the erector spinae at that point. I

strapped him up and he got a certain amount of comfort, but the pain did not disappear so quickly as I had anticipated, and as he still complained of acute pain at the one particular point—namely, the fourth lumbar vertebra—I decided to have this x-rayed.

The condition displayed was a lumbar rib arising from the transverse process of the third lumbar vertebra; it curved down and fused with the transverse process of the fourth lumbar vertebra on the same side. It was also seen in the x-ray photograph that there was a fracture of this rib close to the transverse process of the fourth lumbar vertebra, but the fragments were in good position. I wrote to Professor Robert Howden, Durham University, who for some time has been responsible for the editing of *Gray's Anatomy*, and he informed me that he had neither seen nor heard of a similar condition, although a rib arising from the first lumbar vertebra was not uncommon.

I may say that the patient is a very well developed man, and previous to this occurrence had no knowledge that such a condition existed.

I am indebted to Dr. W. H. Rowden, Leeds, for the skiagram.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TORSION OF FALLOPIAN TUBE.

Torsion of the normal Fallopian tube is an exceedingly rare event. Michael reports a case,¹ and states that only two others are known to have been reported previously. Since then another case has been recorded in the *JOURNAL* (April 4th, p. 657) by Davies. The following is an additional case.

A single woman, aged 32, was admitted to the Rochdale Infirmary on the afternoon of December 4th, 1924, as a case of acute appendicitis. She stated that severe abdominal pain had commenced in the early morning of the same day and she had vomited continuously since. Her periods had always been irregular, the last having occurred nine weeks previously. The pain was referred to the right iliac fossa and to the back of the right buttock in the area supplied by the first lumbar nerve. There was some rigidity over the right iliac fossa. Cutaneous hyperaesthesia was very definitely present just above the centre of Poupart's ligament and to a lesser degree over the area behind previously referred to. On rectal examination a tender swelling was felt to the right of the uterus. The temperature was subnormal and the pulse 100.

A tubal lesion was diagnosed, and on opening the abdomen the right Fallopian tube was found to be twisted, together with an abnormally long mesosalpinx, in a clockwise direction, and to be black, swollen, and intensely congested. The rest of the organs were normal. The tube was untwisted with the greatest readiness and there were no adhesions; it was removed, and the patient made a good recovery. She began to menstruate two days after the operation.

There were thus present in this case the requisite factors which appear necessary to precipitate this occurrence—namely, a long mesosalpinx and the circulatory disturbances caused by premenstrual hyperaemia.

The striking point about the symptoms, to my mind, was the very definite area of pain and cutaneous hyperaesthesia over the right buttock in the area supplied by the first lumbar nerve. The afferent fibres of the tube appear to belong to the eleventh and twelfth thoracic and the first lumbar nerves. In this case, at any rate, its innervation must have been definitely from the first lumbar segment, as the thoracic segments were not affected.

In twenty-seven cases of ectopic gestation leading to either rupture of the tube or tubal abortion, lesions somewhat comparable in severity, I have not observed this sign before.

JOHN C. JEFFERSON, F.R.C.S.,
Honorary Surgeon, Rochdale Infirmary.

PULMONARY OEDEMA IN A CHILD.

A CHILD, aged 4½ years, had been confined to the house, but not to bed, for a few days with a cold, when, while playing on the hearth with other children, clear fluid was seen to gush from her mouth and nose. The mother formed the idea that the child was vomiting. I was sent for, and when I arrived I found frothy colourless fluid oozing steadily from mouth and nostrils. She was cyanosed and restless, and obviously in acute distress, the breathing was laboured and wheezy, the limbs rigid, and the hands clenched. Little air was entering the lungs, the breath sounds were obscured by coarse rhonchi, and the whole chest was dull on percussion. The diagnosis of pulmonary oedema was hazarded, and atropine gr. 1/200 was given hypodermically. In a quarter of an hour there was a decided improvement in her condition, and in half an hour the cyanosis and the flow of secretion had ceased. Before the expiration of an hour the chest was clear on auscultation and gave a resonant note on percussion. At this stage the child fell into a natural sleep which lasted unbroken for six hours.

Beyond a few fine rhonchi in the right chest for a day or two the patient appeared none the worse for the incident. The pupils responded to atropine in a puzzling manner. Both before and immediately after the injection they were widely dilated, but when improvement in the general condition was manifest they were contracted to little more than a pin-point.

RICHARD KENTFICK, M.B., B.Ch.

¹ BRITISH MEDICAL JOURNAL, March 14th, 1925, *Epitome*, para. 237.

want. In the last chapter—on acclimatization—it is shown that oxygen passes more rapidly into an acclimatized person's blood, which therefore more easily reaches an equilibrium with the air in the lungs. Major R. W. G. Hingston's account of the physiological difficulties in the ascent of Mount Everest, given in an appendix, forms a suitable addition to this valuable and exceptionally interesting monograph, the publication of which coincides with the author's appointment to be professor of physiology in the University of Cambridge.

RECENT ADVANCES IN PHYSIOLOGY.

PROFESSOR LOVATT EVANS's *Recent Advances in Physiology*² should be assured of a hearty welcome from practising physicians in this era when the appreciation of the importance of disorders of function has been recognized as a step towards the ideal of medicine—namely, the prevention of structural, and indeed of all, forms of disease; for the time has long passed when, as was felt by the audience of Claude Bernard's lectures in 1870 on experimental physiology applied to the practice of medicine, physiology was regarded merely as a *science de luxe* for which there was not any real need. Professor Lovatt Evans rightly reminds his readers that there cannot be any great theoretical conceptions in medicine without corresponding comprehension of great underlying physiological principles. Physiology has advanced so greatly that, like medicine, it is inevitably breaking up into subordinate special departments; the applications of chemistry have greatly developed physiology, and a similar use of physics should have a like effect in unveiling further knowledge during the lifetime and by the exertions of some of the present generation of physiologists. This volume, which is a worthy successor to *Recent Advances in Physiology and Biochemistry*, brought out in 1906 by L. E. Hill, M. S. Pembrey, and A. P. Beddard, covers a wide field, for it deals with the blood and circulation; the problems of muscular contraction; the active principles of some of the endocrine organs, such as thyroxin, pituitary principles, and insulin; the mechanism of postural reflexes and the functions of the labyrinth, on which Sir Charles Sherrington and Professor R. Magnus of Utrecht have done so much; and on conditioned reflexes, on which the veteran Professor I. P. Pavlov has carried on pioneer work for more than twenty years. At the end of each chapter there are references to authoritative papers, which the advanced student will find useful for even more detailed information.

A few examples may perhaps be given to indicate the general character of the work. While refraining from a final and dogmatic decision on the vexed question of the origin of blood cells, from one common primitive or stem cell (the monophyletic hypothesis) or from an unknown number of stem cells (the polyphyletic hypothesis), he confines consideration to the monophyletic view. The fixed mesenchyme provides, in addition to fibroblasts, the free and the fixed histiocytes, the former appearing as mast cells, the latter or "resting wandering" cells supplying the specialized constituents of the reticulo-endothelial system, and forming an incomplete lining for the sinusoids of the liver, spleen, bone marrow, and adrenal medulla. These cells and their descendants the monocytes have phagocytic properties, which have been also ascribed to all vascular endothelia; this view is not accepted by the author, who considers that the general true vascular endothelium, and also perhaps the endothelium of the serous membranes, more closely resembles the fibroblasts, into which, indeed, they are seen to be transformed in inflammation. Another chapter is devoted to the carriage of carbon dioxide by the blood, in which the ionic interchange is authoritatively explained. The reaction of the blood is then dealt with, and the correlation between the volume output of the heart and the oxygen requirement of the whole body is considered. In the account of the active contraction of the capillaries, Krogh's observations receive full attention, and there is a good illustration of the branching cells described

in 1873 by Rouget; placed on the outside of the capillaries, they are a special form of smooth muscle, and are responsible for the capillary contraction. The nine different effects produced by injection of unpurified "posterior lobe" extracts, and the relation of the pars tuberalis and the hypothalamic region to diabetes insipidus, are discussed. After sketching F. M. Allen's work showing that the β -cells of the Langerhans islets form insulin, the history of its isolation is given, and attention is called to the importance of recognizing that the blood sugar curve is normally subject to variations, and to the problems raised by the method of action of insulin.

But enough or more than enough space has been occupied in attempting to show the interest that this, well written book has for the medical profession.

FRACTURES OF THE ARM AND FOREARM.

THE handsome volume on *Fractures of the Humerus, Radius, and Ulna*,³ with its wealth of illustrations, is a credit to the University of Pennsylvania, in which its authors hold various offices. It is one of a series of surgical monographs published by the New York firm of Appleton and Co. In the preface the authors justify the existence of the book by the changes in our knowledge due to improvements in radiological apparatus and technique which have forced a revision of some of the older ideas concerning the frequency of type and the treatment of certain fractures and epiphyseal separations.

In the chapter on general considerations it is stated that "the more complex the function of a bone the lighter and more delicate it is," and this is alleged to be the reason why the radius is more often broken than the ulna. It is questionable whether either the premiss or the conclusion is acceptable. Is the function of the fibula more complex than that of the tibia?

A chapter is devoted to the osteology and embryology of the long bones of the upper extremity and another to general symptomatology. In this the sound advice is given that "circular plaster bandages are only permissible when completely divided in at least one line." The marked decline in favour of plaster-of-Paris is probably the result of experience gained in the war.

The remaining chapters deal with the several bones and regions and the treatment of complications. A somewhat remarkable omission in a monograph on this subject is the absence of all but casual mention of the calamitous complication of ischaemic paralysis. Some consideration might have been expected of the causes of this condition and the precautions to be taken to avoid it, even if a very strict view of the limitations of their subject precluded the authors dealing with its treatment.

The last chapter, on indications for operative treatment, shows once again how very much more conservative in this respect the practice of surgeons has become since the days before the war, when some kind of plating was much more in vogue. The authors lay down the sound rule that operative or open reduction treatment should only be undertaken when other means fail and when the surgeon feels that he can promise a better functional result. Owing to untiring attention to the technique of operation in its widest sense the authors are able to say that they have had but one infection in plating operations in seven years; that was due to skin abrasion in the original injury. In no case has it been necessary to remove a plate. Yet despite this success they are justified in the statement that "internal fixation is really nothing more than a flimsy makeshift at best, as it is easily broken; absorption soon loosens wires or screws or inlays. Therefore there should be just as rigid care taken with the external fixation as though the case were simply a closed reduction."

The illustrations are many and good, but the diagram of the shoulder-joint on page 59 displays a glenoid cavity more like the acetabulum than the shallow saucer of the scapula.

GUILLAIN'S NEUROLOGICAL STUDIES.

THE first volume of Professor GUILLAIN'S neurological studies was reviewed some three years ago (December 30th, 1922, p. 1269), and it is a pleasure to welcome a second series from the same pen.⁴ Since the publication of the first volume Professor Guillain has succeeded to the chair of diseases of the nervous system in the Faculty of Medicine in Paris, a position of distinction merited by the wide range of his neurological work.

In the present volume he touches many subjects in numerous chapters of varying length and interest. The first six deal principally with a new reflex, designated the "medio-pubic reflex"; the method of eliciting it and its possible value are fully described. The next four chapters are devoted to a study of various cerebral lesions; the most valuable and informing is that describing a case of tumour of the corpus callosum: we have a useful discussion of the symptomatology of these lesions and a bibliography which will be of much use to all who are investigating this somewhat uncommon condition. In one of the longer sections of the book Professor Guillain gives an account of the traumatic lesions of the spinal cord, and has succeeded in presenting a good and succinct account of the principal points of interest and practical value in this important subject, though British neurologists will perhaps disagree with him in certain minor details. We are glad, however, to note a tribute to the work of Head and Riddoch in regard to the reflex activity of the injured cord. Considerable interest attaches to the description of osteo-arthropathies occurring in traumatic paraplegia, a condition of which little, we believe, has been heard in this country.

To disseminated sclerosis a long section is devoted, which may well be recommended to any whose ideas of this disease are bounded by the old conception of the classical picture given by Charcot—a picture which even still dominates some textbooks. Its pathology, clinical manifestations, the changes in the cerebro-spinal fluid, and the etiological problems are all well presented; the whole is a valuable and up-to-date exposition of present knowledge. The secondary degenerations following certain well defined lesions of the cerebrum and mid-brain are next described. A brief note on the occurrence of temporary hyperaemia of the optic disc following lumbar puncture will interest those whose experience has, like the author's, included many patients who have been strangely intolerant of this procedure.

The volume is concluded by eight brief chapters on a diversity of subjects, all of considerable clinical interest, among which we may perhaps mention that describing a form of chronic joint affection following herpes zoster. This second volume of Professor Guillain's neurological studies is a worthy successor to the first, and may be warmly commended to the profession in this country.

A TEXTBOOK OF INORGANIC CHEMISTRY.

THE new edition of Dr. MELLOR'S *Modern Inorganic Chemistry*⁵ has been reset, several sections have been rewritten, and many additions have been made, with the result that the book is nearly two hundred pages longer than the last edition. It provides the student of chemistry with what is probably the best introductory textbook of the subject yet published, full of well selected detail, broad and philosophical in outlook, and written in a style likely to catch the reader's interest.

Dr. Mellor has very wisely incorporated in his pages a great deal of physics, for much chemistry is unintelligible without the illumination cast on it by the science of physics; and his successive chapters, forty-three in number, take the reader on from the simpler and more generalized facts and theories to the most complex, from "Combination by Weight" to "Radio-activity." Much stress is laid throughout on the historical development of chemical knowledge; dates are given, and the evolution of present views is traced wherever possible, a method of exposition

that is by far the most satisfactory to the inquiring mind. Numerous illustrative questions set in examination papers are added at the end of each chapter to enable the student to register the steps in his advancement to knowledge.

The book may be warmly recommended to all students of elementary chemistry; it is well got up, excellently printed, and, as books go nowadays, cheap. Mention may perhaps be made of a few minor errors met with in its perusal: on page 38 the Greek word for "a path" should be "hodos," not "odos"; on page 649 "*spiritus cornu cervi*" should surely be "*spiritus cornus cervi*"; on page 837 the name "A. Mooso" should read "A. Mosso"; on page 955 the quotation ascribed to "Hutchinson" is a quotation from Tennyson ("In Memoriam," cxxii) with several errors of punctuation; on page 1093 "Brinn's" should be "Brin's"; and on page 1096 "Retger's" should read "Retgers'."

NOTES ON BOOKS.

THE general tendency of textbooks of ophthalmology, more perhaps than with other branches of medicine, is to be concerned very largely with problems of pathology and diagnosis; too often the question of treatment, apart from operative methods, is too hastily dismissed. To the practitioner undoubtedly the main interest lies in the possibility of a prompt cure of the condition, and to supply this want Dr. LOEB of Chicago has translated FRANK'S *Ocular Therapeutics*.⁶ The translation is conscientious, and any criticism of the work, therefore, becomes a criticism of the original. The book is divided into two parts. The first deals with different methods of treatment, considered as applied generally or locally to the eye: serotherapy, organotherapy, protein therapy, drugs, and the various applications of physical therapy—light, radium, electricity, heat, cold, and so on. The remainder of the book deals with the various diseases of the eye and its associated parts, a list of possible therapeutic measures being tabulated for each. This resolves itself largely into a mere list of many and various remedies arranged categorically with little or no criticism, constructive or destructive, of their relative merits. From the introduction it would appear that this uncritical attitude is purposely adopted, and that the object of the book is to "give the beginner only a list of remedies which may be used." But without any guidance as to choice, and with little or no information as to indications or contraindications, this would seem to be a somewhat dangerous procedure. The beginner will be the less benefited by such list because a large number of the preparations mentioned are synthetic, which, though they may be known in Germany, are quite unfamiliar, at any rate to the reviewer, and presumably to the majority of English practitioners.

Photomicrography has become an important branch of microscopic work, but is beset by many difficulties when high magnifications, such as those used for the study of bacteria, are necessary. The book which Mr. BARNARD wrote fourteen years ago has been a much appreciated guide to the technicalities of the photography of microscopic objects, and the second edition, entitled *Practical Photo-micrography*,⁷ in which he has had the assistance of Mr. FRANK V. WELCH, will continue the tradition. Since microscopes and cameras of to-day differ but little from those of twenty years ago the authors have not had a heavy task in revision, but they have been able to advise simplification in some apparatus formerly very elaborate. By his recent publication in connexion with cancer Mr. Barnard has encouraged the hope that the scope of photomicrography will soon be enlarged. But no reference is made in this book to the methods and apparatus for using ultra-violet light; another book is promised on this subject.

A translation has now been made by Dr. EHRENFEST of Washington of Dr. ROBERT KOEHLER'S monograph on the treatment of puerperal fever:⁸ we reviewed the second German edition on June 28th, 1924 (p. 1134). The book contains a description of various forms of treatment, with a running commentary on their relative value. Special attention is paid to recent methods, including chemotherapy and protein therapy, and the general tone of the volume is reasonably critical. It contains an index and a good bibliography.

British Medical Journal.

SATURDAY, JANUARY 9TH, 1926.

THE COLONIAL MEDICAL SERVICE.

On October 10th last we welcomed the statement of the Secretary of State for Dominion Affairs and the Colonies that he hoped to create at the Colonial Office an Imperial Ministry of Health. The idea was finely conceived, and the auspices seemed favourable at the moment of its announcement, which followed hard upon the creation of the Civil Research Committee, the report of the East African Commission, and a parliamentary debate on East Africa in the course of which unusual prominence was given by all parties to questions of tropical hygiene, whilst Mr. Amery himself promised the creation at his Ministry of "at least the nucleus" of a Medical Department under a responsible medical head.

This promise, according to answers given in the House of Commons at the end of the session, has not yet been fulfilled, and although the delay may be attributed to reluctance on the part of the Treasury to sanction the necessary outlay rather than to second thoughts on the part of the Secretary of State, it is not so easy to absolve the latter from responsibility for a mistake calculated to check the development of the Colonial health service as perhaps no other single action could. Such a mistake would have been unthinkable had the Secretary of State had the advantage of advice from a medical officer in close touch with the personnel of the Colonial Medical Services, and it is only one more illustration of the crying need for the appointment of such an officer. But even as things stand at present it cannot be pleaded that the decision, taken doubtless without full appreciation of its significance, has been adhered to in ignorance, for Mr. Amery's attention was drawn to the matter by the Dominions Committee of the British Medical Association three months ago, and we refer to it now only because the advertisement of vacancies in the East African Medical Service lays upon us the duty of informing potential candidates for these, and indeed for all appointments made by the Colonial Office, of the position which has arisen. That position is explained on the first page of this week's SUPPLEMENT to the BRITISH MEDICAL JOURNAL. The manner in which the Association has dealt with it will appear more fully from the correspondence which it is hoped to publish at a later date. Meanwhile we can only repeat the trite statement that security of tenure and confidence in the capacity and intention of the Secretary of State to guarantee the rates of pay and conditions of service offered on appointment is one of the chief attractions offered by the Colonial services. Without it recruits of the required calibre will be hard to find. Nor can it be destroyed in Kenya and maintained in Hong-Kong or Trinidad.

Any aspirant for the style of Imperial Minister of Health would do well to remember that the most progressive measure may be introduced in a manner calculated to render it abortive, and that a Minister of Health cannot afford to diminish the efficiency of the medical personnel on whom he must depend for the execution of his policy. We may yet hope that

with fuller consideration of these truths better counsel will prevail at the Colonial Office, and that the projected reorganization on which so much depends will not be much longer delayed.

THE "ANNALS OF EUGENICS."

It is now a good many years since the sons of the eugenic prophets, mourning the loss of Francis Galton, could greet Professor Karl Pearson with the words, "The spirit of Elijah doth rest on Elisha." The output of the Francis Galton Laboratory for National Eugenics has been unrivalled in quality, and has had very few rivals in quantity. The history of pious foundations in England tells many stories of endowments successfully used for ends of which the founder did not dream; some stories of transformations hard to distinguish from breaches of trust; not very many where, although the original intentions of the founder are faithfully carried out, they fulfil an even more useful purpose than he had contemplated. In this select class Francis Galton's endowment has an honourable place.

It is possible that some inconveniences have resulted from the fact that the eugenic work, not only of the Galton Laboratory staff, but of those in sympathy with its objects and using similar methods of research, has been published in more than one journal. The staff of the laboratory has generally published either in *Biometrika* or in separate monographs, and in some instances this will always be the best plan. But there is an obvious advantage in having a journal wholly devoted to the scientific study of racial problems. This fact has led Professor Karl Pearson to undertake the publication of a new journal, the *Annals of Eugenics*,¹ the first two parts of which have recently appeared.

The format of the new journal is, like that of all books printed at the Cambridge University Press, admirable, and the size of page is suitable for the reproduction of charts and pedigrees. The first paper in this issue is a study (to be completed in the next issue) of the characters of Russian and Polish Jewish children in London, by Professor Pearson and Miss Margaret Moul. Its purport is "to discuss whether it is desirable in an already crowded country like Great Britain to permit indiscriminate immigration, or, if the conclusion be that it is not, on what grounds discrimination should be based." The authors suggest that unless the immigrant population attain, on the average, a somewhat higher standard in respect of racially desirable characters than that of the nation receiving them, there is a strong case against unrestricted immigration. They point out that, in the present state of psychological and medical knowledge, it would not be easy to lay down satisfactory rules. A condition precedent is evidently a careful biometric study of the immigrant population, together with that of an adequate sample of our own people. The memoir is an important contribution to knowledge of this kind. It does not appear from the results communicated that the Jewish immigrants do contrast favourably with native Gentile children.

The second memoir is a beautifully illustrated pedigree of epicanthus and ptosis by Dr. C. H. Usher. It is noted that fifteen individuals with epicanthus and ptosis are descendants of an affected male in the direct line. The third paper (also to be completed)

¹ *Annals of Eugenics*. Vol. I, Parts I and II. Edited by Karl Pearson, assisted by Ethel M. Elderton. Issued by the Francis Galton Laboratory for National Eugenics, University of London, and printed by the Cambridge University Press, 1925. (Med. 4to, pp. 255; illustrated. Annual subscription, 50s. net; double parts, 35s. net; single parts, 17s. 6d. net.)

is an analysis by Miss Ethel M. Elderton of data, provided by the medical officers of health for Rochdale, Bradford, Blackburn, Preston, and Salford, regarding infant welfare. Miss Elderton has considered the health and habits of the parents, the condition of the home, the occupation of the father, the place in family, the age of the mother at birth of child, and the employment of the mother, in relation to infant viability. Miss Elderton devotes a good deal of space to a careful discussion of the difficulties likely to be encountered in work of this kind, a discussion which should be read and re-read by those who wish to undertake similar investigations. We would particularly recommend perusal of the very clear discussion of the possible effects of selection on measures of association. We cannot, for instance, assert, without further examination, that because there is no significant association between two characters in a slum population those two characters are not in general significantly associated. We must first ascertain whether the selection implied in the choice of a "slum" population is relevant to the issue. The general sense of Miss Elderton's results is that innate factors are more important than purely environmental factors in relation to infant mortality. The last paper in the issue, by Mr. Anthony B. Hill, deals with Malthus's interpretation of the movements in time of birth rates and death rates. The association is found to be neither distinct nor easy to interpret.

We are sure that this new journal will receive a hearty welcome, and offer the editor and his collaborators our sincere good wishes for the success of the undertaking.

SIR ROBERT BOLAM.

THE announcement that the King, on the occasion of the New Year, has signified his intention of conferring the honour of knighthood on the Chairman of the Council of the British Medical Association has been applauded by all members of the profession, for the recognition of the value of the services he has rendered to it in various capacities is universal. It has naturally given very great pleasure to members of the British Medical Association, whose recent fortunes he has had so large a part in directing. Sir Robert Bolam has, in fact, been concerned in the central administration of the Association for over twelve years; he became a member of the Representative Body in 1913, and of the Council in 1915. In 1920, during the Annual Meeting at Cambridge, he was elected Chairman of the Council in succession to Dr. J. A. Macdonald, who had held office for ten years, including the troublous days of the war. The new Chairman threw himself, not only with zeal, but with zest into the duties of the office to which he had been chosen, and it has been a matter of astonishment to Londoners that he has been able to combine the continuance of active practice in Newcastle with vigorous and unwearying attention to the multitudinous duties which the Chairman of the Council has to perform in London. All members of the Council will agree that his mingled tact and firmness have made him an admirable presiding officer, and members of committees will agree with equal unanimity that he is a most effective as well as regular attendant at their meetings. Not the least of the services rendered by him to the Association has been in the acquisition and equipment of the new House in Tavistock Square, by which the central work of the Association has been greatly facilitated. There is perhaps one more word that should be added. It was said in the address which accompanied the presentation to him of the Gold Medal of the Association, at the Annual Meeting last

year, that he has the rare gift of inspiring affection as well as respect; the extent to which this is true he perhaps does not himself fully realize.

POOR LAW REFORM.

A FURTHER step has been taken in the proposed simplification of Poor Law relief. The Minister of Health has issued to boards of guardians in England and Wales a memorandum of provisional proposals (B32-707) and an explanatory circular (658). Both may be obtained from the Stationery Office, the net price being 2d. and 1d. respectively. On December 12th, 1925 (p. 1136), we referred to the issue of these proposals to county councils and other local authorities, and mentioned some of the more important principles concerned. Opponents of the proposed changes have contended that the activities of the Poor Law guardians have become so specialized as to need the supervision of an authority elected *ad hoc*, but the Minister in his circular to the guardians gives his reasons for disagreeing with this, and for believing that the sympathetic treatment of the poor will not be endangered under the new arrangements. He points out that it will be possible for members of the boards of guardians to serve as elected or co-opted members of the authorities entrusted with Poor Law administration, and that economy and the removal of certain anomalies will be secured. It may be convenient to summarize here the main points of the present proposals. Boards of guardians will be abolished, and their duties, with the exception of the registration of births, deaths, and marriages, will be transferred to county councils and borough councils, the county council exercising general supervision of the administration of all health services, and the borough councils and district councils dealing with detailed work. The registration of births, deaths, and marriages will be undertaken by "electoral registration officers" acting for counties and the county and metropolitan boroughs. Relief to able-bodied persons will be limited and correlated with unemployment insurance; expenditure will continue subject to Government audit. The joint use of institutions by various counties and boroughs will be facilitated. In London the Metropolitan Asylums Board and the Metropolitan Common Poor Fund will be abolished, and the existing staffs, property, and liabilities will be transferred to the London County Council. County councils will submit for confirmation by the Minister of Health a scheme of the arrangements proposed, and it is hoped that there will be no difficulty in securing the concurrence of other local authorities. The existing grants for poor relief, health services, and other purposes will be replaced by a system of block grants to the county or county borough council. Decentralization of the present responsibility of the Minister of Health will follow, and simplification of the financial relations between the Ministry and the local authorities, together with greater freedom for the latter in details of expenditure.

RED CROSS MEDICAL STATIONS FOR SEAMEN.

As those who attended the recent Imperial Social Hygiene Congress at Wembley were reminded, an agreement regarding the international treatment of venereal disease among merchant seamen has been signed by fourteen countries, of which Great Britain is one.¹ Under this agreement medical facilities are to be provided free for seamen in the chief ports of the contracting parties; specialist officers are to be available in the clinics, and a card which can be universally understood is to be used. The agreement, however, deals only with venereal disease, and makes no mention of the broader problem of the health of the

¹ See BRITISH MEDICAL JOURNAL, November 21st, 1925, p. 564.

merchant service as a whole. Norway, as a seafaring nation, has been seriously occupied with this problem, and the Norwegian Red Cross took the initiative in bringing it to the attention of the representatives of other Red Cross societies at the third meeting of the General Council of the League of Red Cross Societies, held in Paris in 1924. That meeting passed a resolution praising the pioneer work undertaken, in co-operation with the Governmental departments, by the Norwegian Red Cross for the improvement of health in the merchant service, recommending national Red Cross societies of all maritime countries to take the matter up, and advising the establishment of Red Cross health centres with clinics for the medical treatment of seamen. In an article in *The World's Health* for January the Norwegian representative, Dr. Harold Engelsen, argues that the provision of clinics for seamen where venereal disease only was treated might keep away some who required treatment, because a feeling of bashfulness might prevent men from applying to a centre generally known to be for venereal disease only, whereas if the centre were under the Red Cross and were known to exist for the treatment of all diseases they would be more ready to apply. Meanwhile the Norwegian Red Cross has established medical stations for the treatment of all diseases among seamen in twenty-one of its seaport towns. These medical stations have been organized on a plan as simple and economical as possible. Usually the chairman of the local health board, who discharges duties similar to those of a medical officer of health, has been appointed to act as Red Cross doctor to treat seamen of all nations applying to him. Moderate rates are charged; in most instances a sailor can pay for treatment, but often does not know where to apply for it. All ships are to be informed where the Red Cross stations are situated, and it is proposed that the doctor shall provide each patient with a small record sheet, with a red cross on it, whereon is inscribed the doctor's name, the name of the centre, the date, and the patient's name, nationality, disease, and treatment. This record would be available to doctors in other ports, and might encourage the sailor to seek treatment again in a foreign port, as it would lessen the difficulty of explaining his case. Dr. Engelsen expresses the hope that the Red Cross societies of other seafaring nations will follow Norway's lead and establish similar stations for the treatment of seamen of all nationalities. The Greek Red Cross has already given practical proof of its interest in the scheme, and the committee appointed to consider it has recommended the opening of Red Cross medical stations in the most important ports in Greece. There is to be a minor health congress in Oslo next summer, at which the Norwegian Red Cross intends to give an international demonstration. It is hoped that it may be attended by many interested in the health of seamen.

PLAGUE IN KUMASI, ASHANTI.

KUMASI, if the photographs portraying the unhygienic conditions in the report¹ before us are representative, must be considered as fortunate in having escaped the ravages of plague for so long. A warning had been given by two distinct outbreaks at Accra in 1908, with 344 cases and a high mortality (over 90 per cent.), but, as with plague and cholera in England in times gone by, a repetition of disaster was necessary to awaken thoroughly the sanitary conscience, which was probably being stirred by the recent arrival of a new medical officer of health. The history of the epidemic of 1924 is briefly told. During April and May it is probable that a few unrecognized cases occurred. In the middle of June the disease assumed an epidemic

character, and in three months there were 140 cases and 121 deaths (86.4 per cent.). It was in all probability originally ship-borne, from eastern ports, Portuguese or French West Africa, or the Canary Isles, to Lagos and thence to Sekondi, or possibly direct to the last without the intervention of Lagos. Undoubted cases occurred in Sekondi early in March, and infected persons could easily reach Kumasi within the period of incubation. Throughout the three months of the epidemic the climatic conditions were ideal for plague, the temperature being between 72.5° and 79.5° F., and the humidity 74 to 75. All types of the disease were encountered—bubonic, pneumonic (primarily and secondarily), and septicaemic. Some of the first were very acute, death taking place in less than twenty-four hours; the case mortality of this form was 78.8 per cent. Nineteen recovered after a stay in hospital of six weeks or so. All 26 who suffered from the primary pneumonic form died, and 24 cases of septicaemic plague all proved fatal in a few hours. One of the latter was a woman seven months pregnant. At the autopsy no signs of disease were found in the foetus, and splenic smears were negative. The suggested explanation that high maternal temperature had killed the foetus in an early stage hardly appears to meet the case. Great credit is due to the medical officer of health, Dr. Selwyn-Clarke, for the promptness and energy with which he formulated and set on foot measures to combat the outbreak, and to the civil authorities in affording all possible help to meet the situation. Though vaccination could not be made compulsory, by exercise of tact most of the population of Kumasi (twenty-five to thirty thousand) were vaccinated; many came also from the surrounding villages, so that in all more than ninety thousand primary vaccinations were performed. The case mortality among those vaccinated prior to infection was 53.1 per cent., as compared with 89.2 per cent. among the unvaccinated. Of the 19 recoveries 12 had been recently vaccinated. These were all bubonic cases. The vaccine was quite ineffectual in warding off a fatal issue in the other forms; 1,434 contacts were kept under surveillance for twelve days; 2.7 per cent. of these contracted the disease, the remainder being allowed to go, with the usual orders to report at once any sickness. Houses, clothing, and effects were disinfected, new premises with the Clayton apparatus, stores and concrete houses by the cyanide fumigator. Excellent examples of the value of antiserum are mentioned where two out of three patients from the same family were treated with it, the other receiving symptomatic treatment only. The former improved rapidly and recovered early; the latter also recovered, but only after an illness of several weeks. The intravenous injection of iodine, formerly recommended, proved quite ineffectual. The usual measures, such as establishing inspection posts on roads of entry and exit, rat destruction (mostly by catchers; poisoning was contra-indicated by the large numbers of domestic animals; the bacillary virus and the Rodier method were not tried), closing of schools and cinemas, and propaganda work were put in force. The report contains an appendix, in which the circulars sent out are transcribed, the prosecutions for contravening quarantine regulations are enumerated, and details of housing conditions, plans, and maps of local interest are given, the whole being well illustrated by photographs. Where so much can be said in favour, a few words of criticism will not, we hope, be resented. The report is very detailed—in fact somewhat overdetailed—and a little more time or care might have been expended in proof reading; lastly, the modern tendency to work out percentages on absurdly low figures, which is here indulged, rather detracts from than enhances the value of a report. For example, we are told that among the police the case mortality was 100 per cent. This is alarming, and might be regarded as further evidence of the unhappiness of the

¹ Report on the Outbreak of Plague in Kumasi, Ashanti. By P. S. Selwyn-Clarke, M.C., M.D., B.S., M.R.C.S., L.R.C.P., D.P.H., D.T.M. and H., Medical Officer of Health, Kumasi. 1925. Government Printing Department, Accra.

policeman's lot, until we find that only one policeman was attacked. Such are, however, minor blemishes, and we can sum up by saying that the account reflects credit on the work of all concerned, and that the outbreak, as on former occasions and in other parts of the world, proved a blessing in disguise, in that it has led to the cleaning up of the district and improvement in hygiene generally—water and food supply, modes of dealing with sewage and refuse, and all that makes for health and well-being and the prevention of epidemics.

APOTHECARIES' SOCIETY: HONORARY DIPLOMA.

H.R.H. THE PRINCE OF WALES, on the afternoon of January 5th, received at York House, St. James's Palace, the Master and Wardens of the Society of Apothecaries of London, and accepted from them the honorary diploma of Licentiate of the Society. The diploma had been prepared and illuminated by Mr. G. K. Gray, and was enclosed in an oblong mahogany casket ornamented with silver and shagreen, made by Mr. Paul Cooper and Mr. H. Soper. In the designing and preparation of the diploma and casket Mr. Oswald Barron, F.S.A., acted as honorary adviser to the Society. The Master, Dr. Vincent Dickinson, with the Senior Warden, Dr. Alfred Hepburn, and the Junior Warden, Dr. R. W. Statham, were accompanied by Mr. Samuel Osborn (a past Master) and Mr. Bingham Watson (the Clerk). Dr. Dickinson, in asking the Prince to accept the diploma, recalled briefly that the society was granted in 1617 a charter by James I, who, in representations made to him by Gideon de Laune, apothecary to the Queen, decided to separate the apothecaries from the Grocers' Company, of which they had hitherto formed a part. The Master mentioned also that the Society of Apothecaries was the only one of the Livery Guilds of the City of London which still practised its "art and mystery," and that by the Apothecaries Act of 1815, and subsequent Medical Acts, its licence was recognized as a medical qualification. The informal proceedings closed with a few words of acknowledgement by His Royal Highness.

PUBLIC HEALTH IN CHINA.

CANTON is said to be the only instance in China of a municipal government endeavouring to establish public health administration on modern lines, and the October issue of the *National Medical Journal of China* is of special interest, since it devotes more than fifty pages to a detailed report of the health of that city. In the same issue, by way of contrast, there appears a sanitary survey of Tsunhwa, a walled town with 50,000 inhabitants, situated 100 miles east of Peking, and retaining the lack of sanitary system characteristic of "old China"; it is probably typical of all Chinese towns with a population of under 100,000, as well as of most of the larger cities. Such surveys are now being made as a compulsory part of the post-graduate study of hygiene at the Peking Union Medical College, and the hope is that by this means great improvements may be effected in the near future. Dr. Chia Ku'ei, in his report on Tsunhwa, explains that the health administration is entirely in the hands of the police force, which numbered 100 to 150 five or six years ago, but has now been reduced to four. There is no special health officer, and the chief of police, even if he possessed the least knowledge of hygiene, has next to no money to spend on it. The main sanitary duties of the police are supposed to be the prevention and supervision of communicable diseases, of which the more prevalent are typhoid and dysentery, but no attempt, in fact, is made to control them. No hospital for infectious diseases exists; there is no quarantine and no notification. Tuberculosis is the greatest single

cause of mortality; cholera is uncommon, but when an epidemic occurs a large proportion of the inhabitants quickly die. In the last epidemic, in 1923, the chief of police issued pamphlets warning against unboiled water, raw vegetables, and fruits, but no action followed. Midwives are unlicensed and extremely ignorant, so that the maternal and infantile death rates are very high. There is no attempt at any form of nursing, school and factory inspection, or supervision of food. The streets are everywhere polluted with human excreta; the city has no sewer system or water supply, and refuse of all kinds is deposited in the yards or streets, where it remains until washed elsewhere by a heavy storm. This calls to mind the descriptions of London about the time of the Great Plague of 1665. In Tsunhwa to-day there is no registration of births, deaths, and marriages; and medical practice is uncontrolled, for doctors are not required to pass examinations or be licensed. An old-fashioned leech usually attaches himself to a drug store. He is not paid for his visits directly, but draws a certain amount of money annually from the store because his patients have to buy their remedies at it. There is no public health relief, and the solitary mission hospital has far too few beds. With a Government in financial difficulties health work on a large scale is out of the question, but Dr. Chia Ku'ei observes that a few simple measures, such as the control of wells and excreta, the prevention of fly breeding, the supervision of medical practitioners and midwives, and the registration of births and deaths, could all be undertaken without much difficulty or expense, and would lay the foundation of better public health. A more pleasant picture is presented by Dr. Li Ting-an's report on Canton, with its population of 800,000; this city is independent of the Peking Government, and has a municipal department responsible for the cleanliness of the streets; for the inspection and regulation of public buildings, including public baths, markets, slaughterhouses, and latrines; for the preparation of vital statistics; and for the registration of medical practitioners, drug stores, and hospitals. It has control of a small public health laboratory, of hospitals for infectious diseases, of one hospital for the insane, and exercises other minor health activities. During last year the money spent on this department is estimated to have been about one-tenth of the whole municipal expenditure, and three-fifths of that for education. No active steps are taken, however, to prevent or treat tuberculosis, but occasional public lectures are given with a view to its prevention. No preventive work against cholera exists until an epidemic arises, when instructions are posted in public places, and a few temporary regulations with regard to the sale of food and drinks are issued. At present there is no organization concerned with infant and maternal welfare, public health nursing, or industrial hygiene. Special treatment is provided for lepers and the insane, and various missionary hospitals and schools carry on very valuable general treatment and preventive work. Public latrines are kept in good order, and house refuse which is dumped in the streets is collected daily by scavengers. Attempts are being made to construct new sewerage, and some old sewer pipes, laid several hundred years ago, have been repaired. All doctors and midwives must be registered before being allowed to practise, but, unfortunately, the licence is often granted to unqualified persons, and the regulations are not strictly enforced. The existence of five small medical schools in Canton tends to improve the local conditions, but the total number of graduates annually is only about fifty, and little attention is devoted to public health in the curriculum. Much delay in improving the sanitary conditions has resulted from the war and political upheaval, but the attitude of the public towards health measures is, on the whole, very good. Small doubt is entertained that very rapid progress will be made as soon as peace is restored.

FOOD CONTROL IN THE UNITED STATES.

It is generally admitted that the arrangements for cold storage in this country to-day fall far short of those in America and other countries, and in discussing on August 22nd, 1925 (p. 349), the new Regulations for preservatives in food issued by the Ministry of Health which are to come into force at the beginning of 1927, we expressed the hope that special efforts would be made to remedy this deficiency. It must not be forgotten, however, that so far back as 1889 such questions received careful attention in England, though ten years elapsed before any active measures were taken. Even so, it may fairly be claimed that this country initiated rather than followed the modern campaign for clean food. The present position in the United States is one of considerable general interest, and therefore a recent report¹ on the supervision of uncooked foods by Dr. H. N. Bundesen, commissioner of health for Chicago, deserves notice. Dr. Bundesen traces the commencement of active measures to 1907, when Rosenau made a list of 317 outbreaks of typhoid fever, 51 of diphtheria, and 125 of scarlet fever, all transmitted by infected raw milk. Since then much attention has been paid to safeguarding the milk supply, and as a result milk-borne epidemics have been considerably reduced both in incidence and intensity. In Chicago no case of typhoid fever, diphtheria, scarlet fever, or other infectious disease has been traced to milk since 1916, when universal pasteurization was put into practice. The efficacy of this precaution was increased by bacterial examination before and after pasteurization, by a strict limitation of the temperature of this process, and by the prevention of contamination of the milk supply subsequently. It was found that the principal sources of such contamination were the imperfect sterilization of the containing vessels, and infection occurring in small establishments where hand bottling and capping were practised. Clean milk was often contaminated by the receptacles in which it was received by the consumer from shops and in restaurants. In Chicago before the end of 1923 one-third of the samples of milk and cream taken from restaurants were found to be deficient in butter-fat, and the bacterial content of the milk was considerably higher than that of bottled milk delivered at private houses. To remedy this an order was made in March, 1924, requiring all milk in restaurants to be served from approved urns, which ensured the proper refrigeration, protection, and mixing of the milk dispensed; as a result the number of "undergrade" milks fell to about 3 per cent. In large cities control of the pasteurization of cream was found much more difficult. A serious factor was the fluctuating demand, the sales of cream being higher at the week-end and falling off during the week, with the result that the cream was often kept long before it was sold. It then had a much higher bacterial content than milk. The danger of such cream, especially if infected with typhoid bacilli, was recognized to be grave, and the Chicago authorities ordered that all cream should be properly pasteurized and labelled with the date of this procedure. The popularity of ice cream in America is very great, and its possible danger as a cause of disease has received more attention there than in England, where the consumption is less. Dr. Bundesen mentions also recent typhoid epidemics in New York, Chicago, and Washington traceable to uncooked oysters. In this connexion it is interesting to recall that at the Cambridge Annual Meeting of the British Medical Association in 1880 Sir Charles Cameron reported cases of serious intestinal disease following the consumption of oysters. The late Sir William Broadbent (JOURNAL, 1895, vol. i, p. 61) reported several cases of the transmission of typhoid fever by them. While most of the principal British oyster layings are now care-

fully protected, the situation in this country is still not wholly satisfactory. There is, however, reason to believe that an oyster kept in clean water for a sufficient length of time will free itself from contamination. In America it was decided that to prevent these outbreaks no one should be allowed to sell oysters without a permit from the local authorities at the place where the oysters were grown or prepared. This corresponds to a proposal under consideration in England at the present time. Dr. Bundesen urges the importance of considering watercress as a possible source of typhoid infection, especially where the danger of contamination by sewage cannot be excluded. Thorough washing of fruit and vegetables with warm water has been found effective in removing soil or other matter containing *B. coli*, but it is not known yet whether this organism found on vegetables is human in origin, and its pathogenicity has not been established. In some lettuces contaminated with *B. coli* the cause was found to be infected ice used in packing. Dr. Bundesen recommends that all vegetables whose freedom from infection cannot be guaranteed should be cooked before they are eaten. The trouble about such advice is that people—at any rate English people—who like lettuce and watercress and cucumber are provoking enough to think that a salad boiled is a salad spoiled, and until we have a Soviet Government they will only eat these things raw.

NEW YEAR HONOURS.

THE New Year honours list contained the following names of members of the medical profession.

Baronetcy.

Sir ROBERT JONES, K.B.E., C.B., F.R.C.S., President of the Association of Surgeons of Great Britain.

K.C.B. (Military).

Surgeon Vice-Admiral JOSEPH CHAMBERS, C.B., C.M.G., M.D., Director-General, Medical Department, R.N.

Knighthood.

ROBERT ALFRED BOLAM, O.B.E., M.D., F.R.C.P., LL.D., Chairman of the Council, British Medical Association.

Lieut.-Colonel FRANK POWELL CONNOR, D.S.O., F.R.C.S., I.M.S.

HENRY ALFRED A. NICHOLLS, C.M.G., M.D., lately Principal Medical Officer, Dominica, Leeward Islands.

C.I.E.

Major ROBERT HENRY BOTT, M.B., F.R.C.S., I.M.S.

Lieut.-Colonel JOHN WALLACE D. MEGAW, M.B., I.M.S., Director of School of Tropical Medicine and Hygiene, Calcutta.

Kaiser-i-Hind Medal of the First Class for Public Services in India.

Miss JESSIE MATILDA ALLYN, M.D., Canadian Baptist Telugu Mission, Pithapuram, Madras.

Miss JENNIE CARLETON, M.D., American Presbyterian Mission, Ambala.

Miss CHARLOTTE LEIGHTON HOULTON, M.D.

Miss SHERIN HORNUMSHAW COMMISSARIAT, Superintendent, Medical Aid to Women, United Provinces.

*PROMOTIONS.**Royal Navy.*

Surgeon Commander ROBERT W. B. HALL, O.B.E., to be Surgeon Captain.

Royal Naval Volunteer Reserve.

Surgeon Lieutenant Commander ALFRED E. W. HIRD to be Surgeon Commander.

Royal Air Force Medical Service.

Squadron Leader FRANK C. COWTAN to be Wing Commander.

The following Flight Lieutenants to be honorary Squadron Leaders: GEORGE S. WARE, EDMOND F. N. CURREY, CHARLES A. MEADEN, FREDERICK E. WILSON.

Sir HENRY CRAIK, K.C.B., M.P. for the Scottish Universities since 1918, and previously for Glasgow and Aberdeen Universities, upon whom a baronetcy is conferred, is an honorary member of the British Medical Association.

¹ Journ. Amer. Med. Assoc., October 24th, 1925, p. 1285.

Canada.

[FROM OUR SPECIAL CORRESPONDENT.]

PUBLIC HEALTH IN ONTARIO.

THE chief officer of health for Ontario is striving energetically to bring about a more effective organization of the public health department, especially in the outlying country districts, and has put forward suggestions well worthy of consideration throughout the Dominion. He compares the progress made in public health in England during the last fifty years with that in Ontario since the passing of the first Public Health Act in 1882, and the establishment of a Provincial Board of Health, and shows that on the whole the comparison is favourable to Canada. The general death rate, for example, in Ontario, was 11.8 per 1,000 in 1923, and the infant mortality rate has dropped from 113.1 in 1900 (the year in which reliable records are first available) to 84.9. The tuberculosis rate has dropped from 148.6 (1900) to 65.6 (1923). The small-pox death rate is negligible, and there has been for several years a steady decline in the deaths from most of the preventable diseases. There is, however, much to be done as regards such causes of death as childbirth, cancer, organic heart disease, influenza, and infant diseases, and Dr. McCullough strongly urges the establishment of whole-time health units, instead of local health administration by small municipalities. As he puts it, "The real basis for local health administration is a competent organization constantly on the job in an area of suitable size and with a population financially able to bear the cost." He shows that there is overlapping of expenditure in the efforts of the Government, the insurance companies, voluntary health boards, and voluntary workers. The co-ordination of medical services, he considers, hinges on the appointment of full-time health officers, as the part-time practising physician will not be seriously regarded as an authority on public health by his medical brethren. He agrees with those who think that the education of the public in matters of health should be initiated and carried out by the local health unit. It is work which must in any case be complicated by the fact that within the boundaries of Ontario 407,000 square miles are embraced. As has been said, this is a subject which is of vital concern to Canada generally, and a recent editorial in the *Canadian Medical Association Journal* commends to the attention of the next conference on national medical services the problems connected with an improved sanitary organization throughout the rural districts of the Dominion. In this connexion it will be of interest to quote the statements of Dr. S. B. Woodward (*Boston Med. and Surg. Journ.*, May, 1925) in making a comparison between the amount of small-pox in Canada and in the various northern States of the Union. He combats the assertion made by health officers of these border States, that the presence of small-pox in their midst is due to its being endemic in Canada, and quotes statistics showing that the number of small-pox cases in every border State exceeded the numbers in the several provinces in Canada. "It is quite clear," he says, "that there is less small-pox in Canada than for man than there is in the United States; that the provinces in Canada have more effectual laws regarding vaccination than exist in the majority of the States; and that we are more a menace to Canada than Canada is to us."

FREEDING OF PRINCE EDWARD ISLAND FROM BOVINE TUBERCULOSIS.

For some time past plans have been in preparation to free the Province of Prince Edward Island from bovine tuberculosis. There was complete co-operation in the matter between the Federal and Provincial Departments of Agriculture, a spirit of willingness which was also found to exist among the cattle-owners of the Province. It was first necessary to secure a two-thirds vote of all the cattle-owners, and this was readily given. The owners realized what an advantage it would be to the island to have all its herds tested, an undertaking which is very easy to carry out, as there is practically only one port of entry, and the importation of stock from outside places can easily

be controlled. The result of this energetic campaign is that Prince Edward Island is now declared to be free of tuberculous cattle. Nearly one hundred thousand head of cattle were examined by qualified Federal veterinary surgeons, and of these less than one-half of 1 per cent. were found diseased, and were at once killed. A very careful quarantine against the entrance of diseased animals is now being maintained.

DALHOUSIE UNIVERSITY.

The teaching facilities of the medical school of Dalhousie University have been greatly increased by the completion of the new pathological building of the Victoria General Hospital, Halifax, for it is at this hospital that the Dalhousie medical students receive instruction in bacteriology, pathology, and public health laboratory work. The building is well designed and equipped in the most modern manner for teaching and the carrying out of research work.

CHILD IMMIGRATION INTO CANADA.

A resolution has recently been passed at a meeting of the Child Welfare Association in Ottawa urging the Government to make more rigid laws regarding the immigration of children into Canada. This was sent to the Department of Immigration, with an endorsement from the director of insane asylums and reformatory schools in the Province of Quebec; in it he referred to the large proportion of inmates of the provincial reformatory schools who were foreign born: last year it was 33 out of 115. The problem was even more grave in the western provinces, where it was found that certain organizations had been responsible for bringing out to this country children of whom a large number were mentally deficient. It is therefore urged that the examination of applicants for admission to Canada be made more thorough, even to the extent of requiring a certified family history of all children.

MEDICAL AFFAIRS IN MANITOBA.

At the last annual meeting of the Manitoba Medical Association the following resolutions were passed, among others: (1) That the Canadian Medical Association be congratulated upon its affiliation with the British Medical Association. (2) That an invitation be sent to the British Medical Association to meet in Winnipeg in 1929. (3) That recommendations be made to the Faculty of Medicine of the University of Manitoba that the number of medical students be limited, together with the adoption of some means of selection of the students admitted. (4) That organized free medical charity be placed under the direction of the organized medical profession. (5) That the question of specialization without adequate medical training be investigated.

Scotland.

GLASGOW WESTERN INFIRMARY.

At the annual Christmas meeting of the Glasgow Western Infirmary, Colonel J. A. Roxburgh, chairman of the managers, announced that the late Mr. Alexander Elder, to whom they owed the extension of the nurses' home and the building of the chapel, had directed his trustees to devote the sum of £100,000 for providing an infirmary or hospital in Govan, near the Elder Park, for poor people. We gave an account of the dedication of the war memorial in the chapel on December 19th, 1925 (p. 1196). It had previously been impracticable for the trustees to proceed with the erection of the infirmary, but a site of twenty-seven acres was acquired some time ago. Interest has meanwhile been accruing on the bequest, with a result that, after paying legacy duty and the cost of the land, the trustees still have £100,000 for the erection and equipment of the hospital and the provision of an endowment fund. The managers of the Western Infirmary are to be the trustees of the hospital, and active building is now in progress. It is intended to provide forty-two beds, but the administrative buildings will enable a larger number of beds to be provided later on when funds are available for further building. As no more than £60,000 will be

available for endowment a considerable annual sum is required to carry on the work in the new building. The new infirmary will be administered as an annexe or auxiliary hospital of the Western Infirmary.

"UNIVERSITY OF EDINBURGH JOURNAL."

The first number of the *University of Edinburgh Journal*, for the autumn term of 1925, has just appeared. This journal is intended to be the official organ of the Edinburgh Alumni Association, an organization designed to foster among former students a spirit of corporate life and to enable them to keep in touch with one another. In a foreword by Principal Sir Alfred Ewing, the hope is expressed that those who have passed out of the University will from time to time contribute accounts of what they are doing and thinking in the greater world—in the life for which their Alma Mater did what she could to prepare them. It is pointed out in an editorial note that the new association does not clash with the interests or functions of existing Edinburgh University clubs, societies, or publications, but that it may be actually helpful to these. Geographical lists of members of the University, including all faculties, are being compiled by the organizing secretary of the Alumni Association, and these will be available to the officials of local societies who may desire to get into touch with all the Edinburgh men in their area. The first issue of the journal includes articles on "New developments in the education department," "The co-ordination of the medical curriculum," "The University settlement movement," and "The Reid symphony orchestra." A list of recent bequests and gifts which have been received by the University is given, and there are several pages of short notes on University news. The editors especially invite information regarding activities of associations of Edinburgh graduates, or of local branches of the Alumni Association at home and overseas. All communications should be addressed to the office of the Alumni Association, Surgery Department, University New Buildings, Edinburgh.

QUEEN VICTORIA'S JUBILEE INSTITUTE FOR NURSES.

It was announced at the annual general meeting of the Scottish branch of the Queen Victoria's Jubilee Institute for Nurses that the successor to Queen Alexandra, who had been patron of the Institute for twenty-four years, was Queen Mary, by virtue of the Royal Charter of the Institute. Lady Mar and Kellie, speaking of the growth of the Scottish branch, said that the cases in the past year nursed had numbered 96,000, an increase of 16,000 upon those for the previous year; the total number of visits paid had been 1,617,000, as compared with 1,500,000. The number of nurses had been 1,746, an increase of 121. The Marquess of Linlithgow, in moving the adoption of the annual report, said that there was much progress and growth, for twenty district nursing associations had been added to the Scottish branch. He added that the particular tendency of medicine and surgery at the present day was not so much a matter of curing as of keeping people well; he believed that if existing medical and surgical knowledge could be made available in all its details to every home in the land, serious disease would be reduced by perhaps 25 or 30 per cent. at once. It was not science which lagged behind, but its administration in the home and the full development of the remedial which science had so far placed at the disposal of mankind. As to finance, he said that the expenditure of the Scottish branch was rising at a faster rate than its income, and there was an increase in the deficit of £945. They must therefore persuade the public to give more support. Sir Leslie Mackenzie, in seconding the report, spoke of the health visiting side of the movement, and of the lines upon which that service was developed in the counties.

ANIMAL DISEASES RESEARCH ASSOCIATION.

The appointment of Professor S. H. Caiger to the new chair in the University of Liverpool, where a department of research in animal pathology is being established, has rendered vacant the post of Director of Research of the Animal Diseases Research Association of Scotland. As will be seen from the notice in our advertisement columns, the appointment now vacant is whole-time and the salary

£800 a year. Applications must be made, before March 27th, to the secretary, Mr. A. R. Milroy, 83, Buccleuch Street, Glasgow. They will in the first instance be considered by the technical advisory committee, who will make its recommendation to the directors of the Animal Diseases Research Association.

EXTENSION OF FALKIRK INFIRMARY.

Speaking at a Christmas fair, held in the Town Hall at Falkirk to raise funds for the new Falkirk and District Infirmary, Lady Findlay of Aberlour referred to the urgent need for the establishment and extension of local hospitals, and congratulated Falkirk and district on the provision it was making, and on the present special effort, which had been organized by the wives and daughters of East Stirlingshire farmers. Within nine months, she said, about £30,000 had been raised by public subscription; with that sum and what would be added by efforts still to come, and with £50,000 which was already at the credit of the infirmary reserve fund, the managers would be able to go ahead with the building of the new hospital, and would at the same time feel quite certain of having the public support to maintain and, if necessary, to increase it.

Ireland.

COUNTY MEDICAL OFFICERS OF HEALTH.

THE Local Government Department of the Irish Free State has issued a circular to county councils drawing attention to the provisions of Section 21 (1) of the Local Government Act, 1925, which laid down that the council of every county shall appoint, with the approval of the Minister, for every county health district in such county, a medical practitioner duly qualified as such, and with such other qualifications as may be prescribed, to be the superintendent medical officer of health, and to be known as the county medical officer of health, with the distinguishing name of such county health district. The Minister is satisfied that the success of the new system of public health administration would largely depend on the proficiency of the persons chosen to fill this position. The possession of the Diploma in Public Health or equivalent degree would be, the Minister indicated, an essential qualification, and should be supplemented by practical experience of administration. With a view to promoting the training of candidates with specialized knowledge the International Health Board of the Rockefeller Foundation made a generous offer to send three medical men, selected by an independent committee, on account of distinguished records of service, to the United States to familiarize themselves with the latest developments of public health procedure. Furthermore, it was recognized that the position of the existing tuberculosis officers possessing the D.P.H. was entitled to special consideration, and arrangements had accordingly been made with the Society of Medical Officers of Health to enable such officers seeking appointment as county medical officers to acquire further administrative experience. These measures were calculated to ensure for the senior positions of the health service of the county a supply of highly qualified competitors. In the circumstances the Minister has decided that, as a condition precedent to his approval, the principle of a selection committee, which had already been found satisfactory in connexion with dispensary posts, would apply to all appointments as county medical officers of health. A bill would shortly be introduced to regulate the future procedure concerning appointments of officers of local authorities. The work in some of the smaller counties would not be such as to afford whole-time employment, and in these cases recourse would be had to a joint appointment with a neighbouring county, accompanied by equitable adjustment of the cost. On the other hand, in a county of extensive area it would rest with the county council to consider the question of subdivision. On various grounds it is considered improbable that the appointment of county medical officers of health could become effective before April 1st next. Notice will be given to the county councils as to the preliminaries with a view to an appointment, but in the meantime it should be

borne in mind that all existing medical officers of health in rural districts have been transferred to the new county sanitary authority, and that consequently the administrative organization for the protection of the health of the community remains intact.

SCHOOL MEDICAL INSPECTORS.

Professor R. J. Johnstone, F.R.C.S.Eng., M.P., on the motion for the adjournment in the Northern Parliament recently, referred to an advertisement of a county regional committee for a medical inspector of school children at a salary of £400. He pointed out that this was an important new service requiring men of experience, and suggested that the Minister for Home Affairs should use his powers of persuasion on the county councils to offer a higher salary. Mr. T. Henderson (Labour) said he did not see why an inexperienced medical man should be allowed to practise on school children, and condemned so low a salary. Sir Dawson Bates (Minister for Home Affairs) replied that the appointment of medical inspector was a matter for the local authorities, but he hoped that the persuasion of the medical profession would ensure that professional men were properly paid.

Correspondence.

PREVENTION OF PUERPERAL FEVER.

SIR,—Many articles and a number of letters on the above subject have appeared in recent years in the *BRITISH MEDICAL JOURNAL*. Not the least important is the article in your issue of January 2nd.

I have always considered that it is possible to demonstrate in a practical way the results of many of the statements which have been made in regard to the means which have been suggested for preventing the occurrence of this disease. We have throughout the country a large number of maternity hospitals and maternity homes, together with some most excellent maternity departments in Poor Law hospitals, to which women go for their confinement who have not been interfered with previously and who have had fair ante-natal supervision. Most of these institutions are in charge of an experienced obstetrician, and they have as good nursing facilities as it is possible to get. If careful records from each of these institutions were put together, one would get a demonstration of what the results would be if the education of the medical profession and of the midwifery nurse were improved, and of the results of midwifery under good aseptic conditions.

I will presume that the results will demonstrate that confinements undertaken under these conditions will show that puerperal mortality can be reduced to a vanishing point. If this can be done it will be more effective in securing for women better conditions than any opinions expressed by our most prominent obstetricians.

I am, of course, aware that at such institutions women are admitted in labour, and that attempts have been made to deliver, and that no ante-natal supervision has been carried out by the hospital or institution, and that among these there occur at the present time a certain number of cases of sepsis. It will be a perfectly simple matter to exclude this group on a definite schedule of conditions which would apply to all institutions keeping records, and if this were done these cases, which must be admitted, would not interfere with the value of the demonstration of treating women under good conditions. The expense of such an inquiry would be negligible. I have on more than one occasion urged this, and still feel sure that such a demonstration would be of the utmost value to the profession.

I am convinced that our efforts should be concentrated on the prevention of the disease, because when it is once developed very little good follows from any variety of treatment at present applicable.—I am, etc.,

JOHN ROBERTSON.

Medical Officer of Health, Birmingham.

January 4th.

SIR,—Mr. Comyns Berkeley (January 2nd, p. 4) has covered the ground pretty thoroughly; but one factor he does not stress is that general practitioners are called upon to do the most difficult and nerve-racking work when they are quite unfit for the job. After a day of ten to twelve hours' hard work the general practitioner goes to bed, entirely weary. At 2 a.m. the bell rings. Out he has to go. Quite likely the car refuses to function until the doctor is almost exhausted by winding the wretched thing. He drives to the patient's house through whatever weather happens to be supplied; and he is confronted by a difficult instrumental case. For assistant he may, or may not, have a competent nurse, who will do all she can; but the doctor must give the anaesthetic, put on the forceps, and hope for the best. If the baby is not born the doctor must slip round to the other side of the bed and give more anaesthetic, and then return to his pulling. I have done it myself scores of times; and always I have cursed my fate, and wondered why general practitioners should be content to continue exposing their patients to such hideous risks.

Often the house conditions are impossible. I have conducted a difficult instrumental case in a house where the sole illumination was a tallow candle. I had to boil my tools by the light of torches of twisted newspaper. And on that occasion my sole assistant was an old woman who was not even passably clean.

So long as midwifery is done by general practitioners who are tired out by a long day's work before they are called out in the small hours, so long will the maternal mortality figure remain high. The general practitioner is asked to do the impossible. Of course, he is an ass to go on doing it. No operating surgeon would conduct a major operation (often more easy than a "forceps case") in a cottage, with inadequate illumination, inadequate assistance, and no anaesthetist. The general practitioner does his best. And for fee?—he may get a couple of guineas; often no fee at all is forthcoming. Money is at the root of the whole trouble. Instrumental midwifery should be carried out in hospital. But there are not enough beds, because there is a lack of money for that sort of thing in hospitals. It is very difficult for an honest doctor not to be an aggressive socialist.—I am, etc.,

Walsall, Jan. 4th.

FRANK G. LAYTON.

FLOATING KIDNEY.

SIR,—Dr. Russell Andrews's instructive address on backache in women (December 26th, 1925, p. 1207), in which he refers to "floating kidney," recalls the unsatisfactory results of operations for fixation, which, as he says, have almost died out during the last few years. Kidneys so loose that they may be almost grasped in the hand when the patient stands and leans forward, have been found on routine examination where no symptoms attributable to "floating kidney" existed. Exercises gave far better results than artificial support, and the latter method is surely the last resort in young women. Our difficulty lies with overworked women and those improperly or under fed, who from disinclination or lack of convenience do not succeed with the exercises. These, however, may be so simple as to be possible in any bedroom, and I venture to mention four: (1) While lying on the back, raise the leg with knee extended and move to right and left, and repeat twelve times. (2) The same, when lying on the face; by placing a sandbag weighing 1 to 3 lb. over the ankle the effort may be increased. (3) While lying on the back with the feet held under a rail fixed to the skirting, or some heavy piece of furniture, raise the body from a sitting position. Here also the effect is to be gradually increased by holding weights in the hands, or, better, carrying the sandbag on the chest suspended by a loop round the neck. (4) For combining pleasure with open-air values, nothing is better than rowing, and this can be obtained by those who can afford it in town parks.

It will be observed that all these exercises bring the abdominal muscles into action. The personal effort involved will be acknowledged by everyone who has given any attention to the matter to be far more effective than massage. One of course realizes that all classes are the better for

the continuous supervision of an instructor, as can be obtained in the gymnasiums, while home exercises are apt to be neglected.—I am, etc.,

London, W.I, Dec. 31st, 1925.

CHARTERS J. SYMONDS.

THE TREATMENT OF ACUTE INTESTINAL OBSTRUCTION.

SIR,—I am glad to see that the remarks of Sir William Taylor, at the last Annual Meeting of the British Medical Association, on the delinquencies of practitioners with regard to the recognition of intestinal obstruction, have received the adverse criticism they deserve, as I regard them as unjust. It is gratifying to note that subsequent speakers did something to soften their asperity.

It is beyond dispute that the diagnosis of obstruction may be a matter of great difficulty in the early stages. It is to be regretted that a leader of surgical thought and practice should indulge in strictures of this nature which appear to be used either for rhetorical effect or as the result of unbalanced enthusiasm. Let me give another example of a similar nature. A few years ago—I am speaking from memory—there appeared an article on the operative treatment of simple fractures, from the pen of another leader of surgical thought, the purport of which was that unless a bone was restored to anatomical alignment the practitioner might deservedly be condemned in damages in an action at law. I am under the impression that the words used were of a more forcible nature.

No doubt in both instances the intention was good, and in both good may result: in the one, by the surgeon being called at an earlier date, and in the other, by more care being exercised in endeavouring to obtain a higher standard of results by the non-operative methods; yet both I regard as damaging to the profession and dangerous in these days when the public is always so ready to blame the doctor and to start actions for negligent treatment on the flimsiest of evidence.

Let us for a moment suppose that every case of threatened obstruction reached the surgeon's hand at the earliest stage before the fatal symptoms are manifest. What would be the result of such an ideal condition? I agree with Sir William Taylor that the results of operation would probably greatly improve, but one hesitates to think what a large percentage of cases would have an abdominal section performed unnecessarily, as doubtless we have all met with cases in which no obstruction has been present at the operation, and on the other hand, cases in which we felt almost certain that obstruction existed that have cleared up to the satisfaction of all concerned without operation. No doubt the surgeon would be satisfied by saying, "Better open a dozen abdomens than fail to recognize one case"; but what about the opinion of the patient and his friends if they were aware of the facts? I rather think that an action might be brought against the surgeon with perhaps more justification than against a general practitioner for not recognizing the serious nature of the case in the early stages, as it would be said, "We sought the advice of the highest in the profession and an operation was performed which was not necessary, and which he as a leading man ought to have recognized was not necessary."

To borrow Dr. Gordon Taylor's words, the moral of the story to my mind is: rhetorical effect should not be indulged in the discussion of a scientific subject, nor should enthusiasm be permitted to obliterate all sense of proportion.—I am, etc.,

London, W.I, Dec. 31st, 1925.

DOUGLAS DREW.

RECENT INVESTIGATIONS INTO THE CAUSE AND TREATMENT OF CANCER.

SIR,—In the *Canada Lancet and Practitioner*, November, 1925, Loudon and McCormack claim to have confirmed the view that the immediate causal factor in carcinoma is the "pleomorphic micro-organism isolated by Glover and Young." They have succeeded in isolating this microbe from a large number of different kinds of cancerous growths. Their investigations have led them to the conclusion that the filterable micrococcus of Nuzum and the filterable elements described by Barnard and Gye are prob-

ably identical with the corresponding forms of the Glover and Young micro-organism, and in this respect their views coincide with the contention which I have urged in the columns of the *BRITISH MEDICAL JOURNAL* (January 10th, 1925, p. 63, and August 8th, p. 271) and in the *Journal of the Royal Sanitary Institute* (December, 1925). My general views on the cancer microbe were set out in the paper published in the *BRITISH MEDICAL JOURNAL* of January 10th, 1925 (p. 60). My former papers appeared in the *Edinburgh Medical Journal* and date from 1921. The investigations therein recorded have convinced me that, whilst this microbe possesses as alternative phases coccal, bacillary, yeast, and hyphal forms, it lives ordinarily in the cancerous tissue as a dispersed element which is so minute as to be invisible. At about the same time as I was carrying out my early investigations in Edinburgh, Glover (in Toronto, as the result of an independent piece of research) was arriving at similar conclusions, which do not seem, however, to have been published till 1924.

Further confirmation of these views is found in two papers by M. J. Scott in the American journal, *Northwest Medicine*, of April and October, 1925. Scott claims to have isolated the Young-Glover microbe from cancerous growths and, in lower animals, to have produced malignant epithelial tumours experimentally at the point of inoculation of the micro-organism. Four monkeys with such experimental growths are illustrated. Furthermore, in his latter paper, Scott claims to have cured a considerable number of cases of cancer with a serum obtained from young horses immunized against an antigen prepared from the Glover-Young microbe. He first commenced the use of the serum over three years ago. The record includes twelve cases, some of which were very advanced.

Case 1, for example, was a woman, aged 39, who in June, 1921, at the Mayo Clinic had a radical removal of the right breast for adenocarcinoma. In May, 1922, she was admitted to St. James Hospital, Butte, with secondary growths in the right axilla and supraclavicular region, involvement of the skin and swelling of the right hand, forearm, and arm. A gland was excised from the axilla and adenocarcinoma recognized microscopically. The treatment was begun in July, 1922, and lasted till May, 1923. "By January, 1923, patient was entirely free from all evidences of carcinoma and free from all swelling and soreness of hand, forearm, and arm, and has remained so to date. Since August, 1922, patient has worked regularly as stenographer, weighs 108 lb., appears perfectly well and states her health was never better."

Case 2 was a woman, aged 50, who had a microscopically diagnosed squamous carcinoma involving part of the face, entire nose, septum, roof of mouth and upper lip, with enlarged cervical glands. The patient was very emaciated and weak; weight 125 lb.; Wassermann negative. The first treatment was given in October, 1923, the last in December, 1924. "By April, 1924, all evidences of carcinoma had disappeared, and by two months later all ulcerated and eroded surfaces had completely healed and have remained healed to date. Present weight 190 lb., colour good; patient appears to be in perfect health, doing own house work and says she never felt better."

Nine other cases are recorded with cancer at varying stages and exhibiting the same improvement under treatment.

In one further case considerable improvement took place, but the patient was subsequently found to have died in another State; Scott says there is no knowledge as to whether or not a post-mortem examination was made.

Scott states that with the experience gained in the treatment of the early cases and the improvement in the preparation of the serum better results are now to be expected, and believes that many of the earlier cases which died under treatment might now be saved. These results of Scott, in my belief, constitute the most important contribution to the non-operative treatment of cancer so far published, but while this new remedy is still in the experimental stage and its full possibilities have yet to be explored it would be unwise to lead the public to imagine that a proved "cancer cure" has been discovered.

The investigations of these various workers are thus seen to confirm in a very complete manner my views on the cancer parasite first published in 1921, and they encourage us in the hope that the knowledge of this parasite which we now possess may be applied with success to the problems of treatment. I have advanced evidence (*BRITISH MEDICAL JOURNAL*, October 27th, 1923, p. 765) suggesting that vaccination with the dead microbe can protect animals in a considerable degree against experimental cancer, and it remains for us to determine how far this procedure can be utilized for prevention in man.—I am, etc.,

Edinburgh, Dec. 19th.

JAMES YOUNG.

THE RELATIONSHIP OF THE MEDICAL PROFESSION TO UNQUALIFIED PRACTICE.

SIR,—After the interesting and important discussion by the Marylebone Division (*BRITISH MEDICAL JOURNAL*, December 19th, 1925, p. 1191) it seems a pity that no formal resolution was submitted to the meeting to crystallize its opinion and act as a guide to the rest of the profession. Perhaps the discussion was too academic and placid to lend itself to so practical an outcome. It is also to be regretted that no member of the public health service contributed to the discussion, speaking entirely from the point of view of the effect of unqualified practice on public health, although it must be admitted that Mr. Bishop Harman's contribution bore in that direction. Dr. Hawthorne's fine exposition of the relationship of the profession to unqualified practice seems to err—if it does err—on the side of a too generous liberality of thought. I gather that he desires the relationship of the profession to the unqualified to be established on general principles, rather than on an analysis of the practice of both kinds of practitioners. According to this view the errors and mistakes of the qualified about balance the "triumphs" of the unqualified, and therefore no relationship can be established on an insecure basis of this kind.

While general principles may be useful guides to the profession in its attitude to the unqualified, they are apt to be mistaken by the public for what it terms "professional etiquette"—the rules of which it believes have been formulated by professional prejudice in the selfish interests of the profession. With all due deference to Dr. Hawthorne, the only way to combat unqualified practice is to expose the methods and practice of the unqualified by what may be termed the analytic method. This method, however, will never be attained until the practice of medicine and surgery is legally restricted to qualified and registered practitioners, and offenders against the law are haled to the bar of justice and there examined and cross-examined with regard to their methods of practice. Quackery thrives on mystery and secrecy, but collapses (like a soap bubble in the sunlight) when the light of a public inquiry exposes its pretensions and humbug.

Take a remarkable eighteenth century example of this—Joanna Stephens's remedies for gravel and stone in the bladder and kidney (see *BRITISH MEDICAL JOURNAL*, May 27th, 1911, p. 1270). So remarkable were the successes attributed to these remedies and vouched for by the highest in the land that Parliament was induced to purchase their secrets for £5,000: in present-day currency probably equal to £25,000. Several leading members of the profession in London of that day—Cheselden, Caesar Hawkins, Samuel Sharp—supported the application. The wonderful secrets when revealed turned out to be a powder of calcined snails and egg-shells; a decoction made by boiling some herb (together with a ball consisting of soap, swine's cress burnt to blackness, and honey) in water; pills of calcined snails, carrot seeds, burdock seeds, hips and haws, all burnt to blackness; soap and honey. When the mystery was revealed the remedy lost its virtue.

The brother of one of my insurance patients, completely blind from dense leucomata in both eyes for the past ten years, consulted an advertising eye specialist in a neighbouring city. He was charged 5s. for the first consultation, one guinea for the second, and half a guinea for subsequent consultations, and was given a small pencil of a dark substance not unlike blacklead to rub into a powder, mix with water, and apply to his eyes. If this treatment was carried out improvement in vision would follow!

A cancer curer in a large Midland town induces his patients to drink their own urine. They do it and some get cured! This instance has not come within my own experience, but it was vouched for by an esteemed medical friend who actually investigated the practice of this cancer curer. The philosophic generalities of Dr. Hawthorne may be good enough for a ruminating profession placidly chewing the cud of reflection in its own "garden," but an active profession, alive to its responsibilities and prestige, will look over the garden wall and see what is going on there.

It was surprising to learn from Mr. McAdam Eccles that Mr. George Bernard Shaw had so impressed his London audience that they even wished that they had never become

qualified and registered. It may be that Londoners are more under the influence of Shavian logic than those who live further north. Mr. Shaw, in a letter to the *Times* of October 23rd, 1925, dealing with the General Medical Council and Mr. Axham, in order to combat an allegation that he had "a down on doctors," stated, "few persons can have had more or better doctor friends than I; indeed, that is why my utterances have been so well informed." Further on in the same letter he informed the public that when he and his wife were ill as the result of an injury they had to seek the help of the unqualified and unregistered—to wit, Sir Herbert Barker and an American doctor of osteopathy at Birmingham. From this information one gathers that when the Shavian intellect requires fodder to castigate the profession, Mr. Shaw gets it from his registered medical friends—gratis, I suppose; but when the Shavian body requires treatment he gets it from the unregistered—for a fee commensurate with the time, skill, and responsibility involved. Mr. Shaw may not be "down on doctors," but he gives them an inordinate amount of his attention. Perhaps he chastens because he loves them and desires to exorcise their foibles and stupidities. It would be a change, however, if he turned his versatile intellect in another direction, and gave us a play with the quack as hero. A play based on James Graham and his Celestial Bed would make an excellent draw if it could pass the censorship of the Lord Chamberlain.—I am, etc.,

Warrington, Dec. 21st, 1925.

J. S. MANSON.

PALE BABIES AND DEEP PERAMBULATORS.

SIR,—While I quite agree with the authors of the note on "Pale babies and deep perambulators," published in the *JOURNAL* of December 26th, 1925 (p. 1224), I would like to suggest another reason for the improved colour of the baby's cheeks. I suggest that the diet, in this case, is very far from being suitable, and the colour is a danger signal and not a sign of health.

In the first place, 5½ oz. of milk and 1½ oz. of water, or 7 oz. feeds for a baby 2 months old, is far too large a volume. The capacity of the stomach at this age is 3.37 oz. In the second place, assuming that there are six feeds in the twenty-four hours, the baby gets 33 oz. of milk, giving 660 calories; and if sugar is added probably about 750 calories are given, or sufficient for a baby weighing 15 lb. The baby's weight is not stated, but at 2 months the average baby weighs about 10½ lb., and requires 512 calories (50 calories per pound of body weight). In this case, then, the baby has at least 200 calories above the normal requirements.

I suggest that the increased colour of the cheeks is an effort to eliminate the excess of calories as radiated heat, by flushing the exposed part of the body with the overheated blood, and the better circulation of air round the body, obtained by raising the baby in the pram, would tend to increase the circulation of blood in the exposed parts.

Babies living in the open air certainly require a more generous supply of calories, and so can digest a larger quantity of milk than those living in a warm atmosphere; but I repeat that it is wise to observe that an increase of colour in the exposed parts of the body may be a danger signal and not a sign of improved health.—I am, etc.,

B. A. ASTLEY WESTON, M.B., Ch.B., D.P.H.

Wellington, Shropshire, Dec. 28th, 1925.

NASAL DOUCHING.

SIR,—Dr. Coyne's letter on this subject (January 2nd, p. 37) ends with the question, "Are we going to tell our patients that nasal douching is dangerous?" Personally I am *not*; but I am going to point out to them that they must let the solution trickle out and on no account blow the nose until the fluid has disappeared, otherwise they will blow the diluted discharge into the Eustachian tubes. I am inclined to think that a watery agent is apt, after prolonged use, to thicken the mucous membranes and I prefer an oily one.—I am, etc.,

London, W.C.1, Jan. 5th.

GRAHAM GRANT.

Obituary.

LOUISA ALDRICH-BLAKE, D.B.E., M.D., M.S.,

Dean of the London School of Medicine for Women.

A brief announcement was made in the *JOURNAL* of last week of the death of Dame Louisa Aldrich-Blake, which unexpectedly occurred on December 28th, 1925, at her house in Nottingham Place, Marylebone. Although for some little time past her health had caused anxiety to her friends, yet it was characteristic of her reticence regarding her own trouble that only those who were most intimate with her were aware of her condition. Up to the last she was engaged in active work. She was operating at the Royal Free Hospital a month previously, and had attended a School Council meeting only a week before she died.

Louisa Brandreth Aldrich-Blake was the daughter of the Rev. F. J. Aldrich-Blake, and was born in 1865 at Chingford, Essex, of which parish her father was at that time rector. She was educated chiefly at home and then for a year and a half at Cheltenham Ladies' College, where she passed the Preliminary Scientific Examination (now the First Medical). In 1887 she entered the London (Royal Free Hospital) School of Medicine for Women, and in 1892 she passed the examination for the M.B. degree of the University of London with first class honours in medicine and obstetric medicine. In the following year she graduated B.S., also with first class honours, and qualified for the gold medal. She obtained the degree of M.D. Lond. in 1894, and the M.S. Lond. in 1895. She was the first woman holder of the latter degree.

In 1895 Miss Aldrich-Blake was appointed assistant surgeon at the Elizabeth Garrett Anderson Hospital. She became full surgeon in 1902, and senior surgeon in 1910, which post she only relinquished at the beginning of 1925, but still remained on the consulting staff. She was the first woman to hold the posts of surgical registrar, anaesthetist, and lecturer on anaesthetics at the Royal Free Hospital; she held these posts for several years. Soon after the war Miss Aldrich-Blake was invited by the Royal Free Hospital to become a member of the consulting staff. She discontinued her active surgical work there only about a month before her death. In February, 1906, Miss Aldrich-Blake had been appointed Vice-Dean of the London School of Medicine for Women. She succeeded Miss Cock as Dean in 1914. Despite the distinguished positions she held elsewhere, Miss Aldrich-Blake for many years continued as surgeon to the Canning Town Women's Settlement Hospital. The distance was considerable and the eastward journey must have been irksome, yet the house-surgeon could always

depend on an immediate and willing response to a call for Miss Aldrich-Blake's valued help.

It is difficult to realize how one individual could have successfully accomplished all the war work which Miss Aldrich-Blake undertook. Immediately upon the outbreak of war she was very active in equipping a group of medical women who were prepared to go to Brussels, but, as it eventually proved impossible to establish a hospital there, the unit began work at Château Tourlaville, near Cherbourg, in the autumn. She herself worked at this hospital during the Christmas vacation, 1914-15. During the summer vacations of 1915 and 1916 she worked at the hospital at Royaumont of which Miss Ivens was in charge, thereby relieving her for a time. In the spring of 1916 Miss Aldrich-Blake approached all the women on the *Medical Register*. From the replies received, eighty women were sent to

hospitals in Malta, Egypt, or Salonika in August and September, 1916. In October, 1916, on hearing from the War Office that fifty more medical women were needed for service with the R.A.M.C. in English hospitals, Miss Aldrich-Blake again negotiated with all the women who had qualified in the preceding ten years, and secured the requisite number in a very short time. While she was thus supplying and equipping doctors, and herself acting as relief in her own vacation time, she was also doing double duty at the Royal Free Hospital. She continued this work until the return of the regular surgeons in 1919. She was also visiting surgeon to the W.A.A.C. Hospital at Isleworth throughout its existence, and consulting surgeon for the women patients at the Herbert Hospital, Woolwich. All this extra work, in addition to her own private practice, was quietly and unostentatiously accomplished. Her work received

DAME LOUISA ALDRICH-BLAKE.
(After the portrait by Sir William Orpen, R.A.)

Royal approval when she was created Dame Commander in the Order of the British Empire among the New Year Honours of 1925.

Miss Aldrich-Blake contributed an article on "Pain as a symptom of pelvic trouble" to the *Practitioner's Encyclopaedia of Midwifery and Diseases of Women*, and an article on "Abdomino-perineal excision of the rectum by a new method" to the *BRITISH MEDICAL JOURNAL* in 1903. She had long been a member of the British Medical Association, and at the Annual Meeting at Bradford in 1924 she held the office of vice-president of the Section of Obstetrics and Gynaecology. She was an active and valued member of the Reception Committee which had charge of the arrangements in connexion with the Royal opening of the Association's new House in London last summer, and in that capacity was one of those presented to the King and Queen during the ceremony on July 13th.

None worked harder than the Dean for the accomplishment of a fitting memorial of the jubilee of the London

School of Medicine for Women—namely, the establishing of three chairs. At the jubilee dinner held in the Guildhall in 1924 striking testimony of the affectionate regard of students past and present was given. When the Dean rose to speak repeated cheers were given in an outburst which, on retrospection, seems to have been accompanied by more than usual emotion. Dame Louisa Aldrich-Blake's professional work was distinguished by an efficient thoroughness which, coupled with her characteristic self-effacement, gave to her personality its distinctive charm. As colleague, teacher, and dean she will be mourned by all the medical women and students who had the honour to be associated with her.

The funeral took place on January 1st from the School of Medicine for Women, the service being held at St. Pancras Church. After the cremation the ashes were taken to Dame Louisa's home at Welsh-Bicknor, Ross, Herefordshire. A message of personal regret and sympathy was received by the School of Medicine for Women from Her Majesty the Queen, expressing the loss she feels has been sustained by the profession. Many were the floral tributes sent from various associations and groups of people expressing the affection held for her by those with whom she had worked. The funeral service was attended by representatives of all the institutions with which Dame Louisa had been connected, and of many medical bodies and charitable organizations, together with a large number of medical men and women who had been associated with her in professional or private life. The University of London was represented by the Vice-Chancellor, Professor Gardner; the Royal College of Physicians by the President, Sir Humphry Rolleston, Regius Professor of Physic at Cambridge; the Royal College of Surgeons by Mr. Walter Spencer, Vice-President; the Ministry of Health and the Board of Education by Sir George Newman; the Royal Society of Medicine by the President, Sir St. Clair Thomson; the British Medical Association by Dr. Christine Murrell (member of Council) and Dr. C. Courtenay Lord (Assistant Medical Secretary); and the Medical Women's Federation by Dr. Jane Walker and Miss Frances Ivens.

The following appreciations of the work and character of this most distinguished medical woman have been contributed at our request by colleagues and friends:

Miss M. M. CHADBURN, M.D., B.S., senior surgeon, South London Hospital for Women; late surgeon, Elizabeth Garrett Anderson Hospital, writes:

As one of the few medical women who entered the London School of Medicine for Women on the same day as Dame Louisa Aldrich-Blake, and one who has been her colleague ever since, until her too early and much lamented death, I would add my tribute to her memory.

My recollection of Miss Aldrich-Blake as a student was that of a shy, quiet, steady, solid personality, invariably producing brilliantly good work without any fuss or trouble. It soon became evident that to specialize in surgery was her aim, and I remember we thought her lucky in that owing to private means she could afford to wait the opportunity. She did not have to wait, however, as the only opening to practise surgery as a specialist likely to occur for years came at the right moment in her career, and she was appointed surgeon to the Elizabeth Garrett Anderson Hospital (then the New Hospital for Women). It was equally as fortunate for the hospital to have secured Miss Aldrich-Blake's services as it was for the inexperienced brilliant young aspirant to surgery to have acquired her opportunity of which she was to make such splendid use.

Miss Aldrich-Blake qualified at a time when opposition to women in the profession was still very marked, and here again she was a source of strength to the cause; any work she did was sure to be good; her serenity, equanimity, and self-reliance could stand the jars undisturbed which might have upset the even tenor of work for many people. Happily combined in her character were capacity for great intellectual achievement, a grave sense of responsibility, and real administrative power. She was impartial in judgement, just even towards what she most disliked or disapproved. I have often, in her younger days, heard her described by her senior colleagues as "a pillar of strength."

The shyness of her younger days to a great extent wore off with time and the necessities of her prominent position and varied experience, but by nature she was shy and quiet, rather than retiring. She was ready to do all the work that came to her hand, but it came to her rather than that she sought it, and it came to her because of the excellence of her doing. Her physique was such that hard work was easy to her.

Miss Aldrich-Blake was not a fighting pioneer, as Miss Jex-Blake and Mrs. Garrett Anderson had to be, but she was a necessary sequence to their work if the position of medical women was to be established—a pioneer in solid, brilliant work, a pioneer whose character influenced for good all who came in contact with her, and one to whom, fortunately for her, it fell to demonstrate rather than to fight. I doubt if she could have fought actively; it was not in her nature, though she could certainly sit tight and hold on against opposition, and this without any ill will to those fighting her; she expected the truth to win by its own weight.

I have known her work well and intimately all her working life, and never known it to fall below the best; second best was unknown to her. She was not a quick thinker, but her judgement was excellent. She gave full time and thought to every case, whether minor or major. As an operator she was bold, courageous, level-headed, thoughtful; her hands were good to watch at work—her finger-tips obviously carried brains in them. Miss Aldrich-Blake was one of the first English surgeons to do Wertheim's operation for carcinoma of the cervix uteri (see *BRITISH MEDICAL JOURNAL*, 1905, vol. ii, p. 699); she also developed and improved the technique of the abdomino-perineal route of excision of the rectum.

Miss Aldrich-Blake was loved, admired, and esteemed alike by colleagues, patients, and friends. As Dean of the Women's Medical School she was very popular with the students; her character and attitude towards her profession was a profound influence for good among them. It can be truly said of her that she has joined

"the choir invisible
Of those immortal dead who live again
In minds made better by their presence: live
In pulses stirred to generosity,
In deeds of daring rectitude, in scorn
For miserable aims that end with self,
In thoughts sublime that pierce the night like stars
And with their mild persistence urge man's search
To vaster issues."

Lady BARRETT, C.B.E., M.D., writes:

Dame Louisa Aldrich-Blake was one of the first medical women in active practice whom it was my privilege to meet when I entered hospital as a student. I remember she impressed us all as being a woman brilliant in surgical work, level-headed in judgement, and singularly unconscious of herself or of possessing unusual ability. We took it for granted that her help was always available for any who (as she would have put it) thought it worth having. She was somewhat shy and reticent, alike to colleagues and juniors. This characteristic made it perhaps difficult for many to know her intimately, but by all she was entirely trusted. This has been proved in the course of many years by the number of her colleagues who turned to her instinctively when needing surgical help for themselves. As Dean of the London (Royal Free Hospital) School of Medicine for Women she has done a great work. Her balanced judgement and sympathetic appreciation of both sides of debatable questions have been invaluable in the deliberations of the council for over ten years, and her selfless outlook on life has enabled her to be a unifying influence, drawing ever closer the bonds between the educational work of the Medical School and the philanthropic side of the hospital. She has set a high standard for all who follow after.

Dr. ARTHUR G. PHEAR, C.B., senior physician to the Royal Free Hospital, writes:

Dame Louisa Aldrich-Blake was one of those rare and noble characters for whom self-interest counts as nothing. She was indifferent to worldly success, yet to her came, unsought, professional success and worldly distinction in no small measure. Her dominant motive was service, and

throughout her active life she devoted herself to the welfare of the medical school of which she was dean, and of the two hospitals on the staffs of which she served as a distinguished member. Perhaps it was in the fulfilment of her responsibilities as Dean of the London School of Medicine for Women that she found her greatest opportunities. Here indeed she proved herself one of those who "give counsel by their understanding." She was accessible to all, and all came to her, students and staff alike, when they were in any difficulty, assured of a sympathetic hearing and of wise and helpful advice. She found ample scope for her unusual administrative faculties on various committees of both school and hospital, and her insight and wide experience were of great value in promoting the harmonious working of the two separate, though co-ordinated, institutions. Of her it might have been truly said that "labor vitæ vita est," and to her life's work she brought human qualities of sympathy and a wide understanding that endeared her to all with whom she had to do. From her devotion to the interests of others there sprang a measure of serenity and happiness that lasted to the end, undimmed by the suffering of her later days, and the memory of her example and personality will remain as an enduring help and encouragement to all who knew her.

Dr. MARX SCHARLIEB, C.B.E., President of the London (Royal Free Hospital) School of Medicine for Women, writes:

From her student days Dame Louisa Aldrich-Blake was always remarkable for her unselfishness, modesty, and truth. Great as she was as a surgeon and as an administrator, she was far greater as a guide and leader among medical women and students. All this was clearly demonstrated during the last difficult and painful eighteen months of her life. She knew her fate, and she suffered much disability, but never once did she falter, never once was she wanting in cheerful performance of her manifold duties. Her winning smile and serene gaiety of manner persisted to the very end, and one of her last acts was to secure yet one more benefit to the hospital she served so well.

RICHARD CATON, C.B.E., M.D., F.R.C.P.,

Emeritus Professor of Physiology and Consulting Physician, Royal Infirmary, Liverpool.

It is with great regret we have to record the death, at Haslemere, Surrey, of Dr. Richard Caton, one of Liverpool's honoured citizens and a highly esteemed member of our profession. His health during the past six months had not been good, and he suffered from sciatica, which greatly impeded his usual activity. Mentally alert, he sought the South to escape the chilly months of the North; although retired from medical practice, he continued to take a keen interest in the university, and was an active member of the University Council down to the time of his death.

Dr. Richard Caton belonged to a Lancashire family originating in Heysham and Caton. He was born in 1842, and received his general education at Scarborough Grammar School, where he developed a taste for classics which he assiduously cultivated throughout his life. He received his medical education at Edinburgh University, where he graduated M.B., Ch.M. in 1867. In 1868 he settled in Liverpool, and was soon identified with the Liverpool Royal Infirmary School of Medicine, and had his share in its development into the Medical Faculty of the University College of Liverpool. In 1870 he became M.D. Edinburgh, receiving the gold medal for his thesis on migration of leucocytes. Dr. Caton did some original work on localization of movements in the cerebrum in the early seventies, and owing to his interest in physiology was appointed lecturer in that subject in the then School of Medicine. This post he held until the Holt chair of physiology was founded, when he became the first professor of physiology in the new University College. When he relinquished this chair he was succeeded by Professor Francis Gotch, and was accorded the title of Emeritus Professor for his long and distinguished services. Dr. Caton was one of the most active promoters of university education in Liverpool. He was a seer in this respect, and the idea of the University College being one of the constituent colleges of Victoria University, Manchester,

received his full support. This connexion existed until 1903, when the University of Liverpool was founded and the University College merged in it. His interest in university education in Liverpool did not diminish. He served the university in many capacities; he was its first representative on the General Medical Council, and held that office down to the time of his death. He had also been Pro-Chancellor.

Dr. Caton was a painstaking physician and a good teacher in clinical medicine. He paid special attention to diseases of the heart, and published an interesting and suggestive monograph, *Prevention of Valvular Disease of the Heart*. He took great interest in the foundation of the new Heart Hospital shortly to be opened in Liverpool. He warmly supported the cause, and recognized at the outset the importance of such a hospital for diseases of the heart. When he retired from the active staff of the Royal Infirmary he was appointed consulting physician, and afterwards held the office of president. In the Liverpool Medical Institution he held the office of vice-president in 1881 and president in 1896, and celebrated in 1919 the jubilee of his membership. His public services were recognized by the Universities of Liverpool, of Edinburgh, and of Padua by the conferment of the LL.D. degree. At Padua Dr. Caton represented the University of Liverpool at the 700th anniversary of the foundation of that famous seat of learning.

Dr. Caton was keenly alive to the importance of a high standard of public health, and his name has been associated with every form of progress in the city. A man of such varied interests and accomplishments naturally attracted the attention of the civic rulers, and in 1907, amid universal approval, he was chosen Lord Mayor of the city. If Dr. Caton was a party man he was so only for the advancement of the well-being and welfare of the city. As long as progress was being made he cared little which party performed it. He realized the importance of example and the constant reiteration in the most telling language of the rules of health. He ever insisted on the personal equation, and reminded all and sundry that slums were due in large measure to the ignorance of the rudiments of personal health. Dr. Caton travelled a good deal and was fond of mountain climbing. His fondness for the classics brought him the chairmanship of the Liverpool branch of the Classical Association, and he was a member of the Hellenic Society. He travelled in Greece and published papers on *The Temples and Ritual of Asclepius, Hippocrates and Cos*, and *The Medicine and Medicine God of the Egyptians*.

Dr. Caton took a great interest in the cathedral, and was at one time joint honorary secretary of the executive committee. During the war he was honorary colonel, West Lancashire Division, R.A.M.C., and was indefatigable in his efforts for securing the comfort and nursing of the sick. He was chairman of the Nursing Service Committee (Liverpool branch), British Red Cross Society, and in March, 1920, received the decoration of C.B.E. in recognition of his services.

As a man to meet for the first time his affability was a striking feature; he had the happy knack of placing new acquaintances at their ease. Singularly free from pettiness of mind, he made full allowance for the foibles of human nature. Generous almost to a fault, he did a great deal of quiet unostentatious charity, and many have been relieved in their necessities, never knowing who the generous friend was.

Dr. Caton married the daughter of the late W. S. Ivory, W.S., of Edinburgh. Two daughters were born, one of whom is the wife of Professor Ormerod, professor of Greek at the University of Leeds. Dr. Caton had been a widower for some years; but his life had been rendered happy by the solicitude of his daughter. Dr. Caton leaves behind a host of sorrowing friends in all ranks of society, a fragrant memory of a life well spent, a race well run, and an example to be followed by all who love their fellow man.

Dr. V. C. DE BORNVILLE (Liverpool) sends us the following tribute to his memory:

As one who has been intimately associated with the late Dr. Caton, as his family physician, for the past eighteen years, I venture to write these few lines. In Dr. Caton,

as all who knew him will agree, there has passed from our midst a great man, a good man, and a gentleman. It is doubtful whether our profession, in spite of its high calling, and all that it does to bring out that which is great, good, and gentle in human character, has ever brought forth a man in whom these fundamental qualities taken together were more highly developed. His genial and remarkable personality imprinted itself upon everybody who came in contact with him, but only those who knew him best could appreciate his determined yet humble devotion to duty in the service of his fellow men, and, it should be added, of his God. Even when much too ill to work, he was not satisfied unless he was doing something in response to this high calling, whether in relation to national, civic, or professional betterment; and it was a bitter disappointment to him when he was with difficulty persuaded to leave Liverpool and to go to Haslemere, in the hope—alas! in vain—that his old and failing body would outlive yet one more winter. But though his body was old his mind was ever young, full of knowledge whose mass was unresistingly driven as by some divine force always to be helping his city, his nation, his race. His familiarity with anthropology, archaeology, the Bible, the classics, and modern science, kept that broad mind in touch with the line of continuity that has made the human intellect what it is to-day, and rendered him a master as well as a student of human nature. But he was also able to look beyond all those mental impressions which permit of analytic perception, and to probe into what he believed, and, by example, made others feel, to be the divine sphere of reality itself, showing, not by argument nor by attaching himself to the unsatisfying tenets of any particular philosophical doctrine, but by sheer force of character, that religion and science are not incompatible. For he never worked for self-advancement nor from selfish motive, but with singleness of purpose accompanied by a delightful sense of humour and charming friendliness he lived to do good and did it, making all his hard labours, his great learning, and his inimitable gift of refinement subserve that one end.

JOHN GRAY MCKENDRICK, M.D., LL.D., F.R.C.P. Ed.,
F.R.S.,

Emeritus Professor of Physiology, Glasgow.

THE death took place in Glasgow, on January 2nd, of John Gray McKendrick, Emeritus Professor of Physiology in the University of Glasgow. He was born at Aberdeen in the year 1841, being the only son of James McKendrick, merchant of that city; he received his education there, and graduated M.D. in 1864. His original intention was to engage in general practice, but while acting as surgeon in the hospital at Fort William he met Dr. Hughes Bennett, at that time professor of physiology in the University of Edinburgh, who offered his assistantship to Dr. McKendrick. The post he accepted, and soon gained for himself a great reputation as a teacher. For some time also he acted as a lecturer on the institutes of medicine in the Extra-Academical School at Edinburgh. He joined the Royal College of Physicians at Edinburgh as a Fellow in 1872. In 1867 he married Miss Mary Souttar, daughter of Mr. W. Souttar of Aberdeen. In 1876, on the death of Professor Andrew Buchanan, he was elected to the chair of physiology in the University of Glasgow, and in this post he spent thirty years, retiring in 1906. In Glasgow he gained a great reputation, both as a teacher and as an observer of physiological facts. Besides the work of regular teaching of medical students he found time for much original research, showing, as the titles of his published communications indicate, particular interest in the peripheral nervous system and the special senses. The development of the physiological department at Glasgow University owes much to his energy. On the death of Professor Bennett, Professor McKendrick had purchased his apparatus and diagrams for the benefit of the class in Glasgow University, and to his encouragement of physiological research is largely due the great development which has taken place in recent years in this department of Glasgow University.

He was a Fellow of the Royal Societies of London and Edinburgh, and the Universities of Aberdeen and Glasgow had both recognized his contributions to science by conferring upon him the honorary degree of LL.D. During the course of the active period of his life he had at various times held the post of examiner in physiology at the Universities of London, Edinburgh, Birmingham, Oxford, Cambridge, and Durham. He was for a time Fullerian Professor of Physiology to the Royal Institution of Great Britain; he twice delivered the Thomson Lectures at the Free Church College of Aberdeen, and for a time acted as one of the lecturers in connexion with the Gilchrist Trust. When the British Association met in Glasgow he was president of its Physiological Section, and he had served on the councils both of the Royal Society and of the Royal Society of Edinburgh.

Two years after becoming professor of physiology in Glasgow he published his *Outlines of Physiology*; which attained a great success, and in 1888 he produced his well known *Textbook of Physiology*. The first volume, "General physiology," appeared in 1883, and the second, "Special physiology," in the following year. In 1879 he had published his lectures on the history of physiology, and in 1892 he brought out *Life and Motion*, a contribution to the relations subsisting between nerve and muscle. He contributed many papers on physiological subjects to current scientific literature, of which most appeared in the *Transactions and Proceedings* of the Royal Societies of London and Edinburgh; among the most valuable of these were papers dealing with physiological acoustics and experimental phonetics. Many of his books and papers were of high literary quality, although almost all he wrote had more or less connexion with his own special subject of physiology. Among these are included a *Life of Helmholtz*, which he produced in 1899, the *Boyle Lecture on Hearing*, delivered at Oxford in 1899, *Science and Faith*, also produced in 1899, and *Christianity and the Sick*, which appeared in 1901.

During the early days of his assistantship at Edinburgh he came to a great extent under the influence of John Goodsir, who was professor of anatomy, and of John Hughes Bennett, who occupied the chair of physiology. These master minds in medical research exercised a great influence upon his future attitude towards scientific inquiry. His subsequent work with Sir James Dewar, which showed that light produced electrical changes in the retina, was a contribution of the highest value to physiology. He was also one of the earliest workers upon the relation of chemical constitution to physiological action, which had a most important bearing on the development of pharmacology. Following Carl Ludwig, he was one of the earliest in this country to introduce graphic methods in recording physiological observations, and he used them especially in demonstrating the relations between nerve and muscle, which formed one of his most important lines of research. Another important study which he undertook was the explanation and experimental illustration of Helmholtz's work on the theory of musical and vocal tones. For this purpose he showed how the curves on the wax cylinders of the phonograph, reproduced on a magnified scale, illustrated the theories of sound and voice-production.

Perhaps Professor McKendrick's most outstanding gift was that of clearness and aptness of illustration, which made him a valued and popular lecturer. He had the ability of making his subject of intense interest to his students and attracting their attention. The same qualities gained for him the various appointments, which we have already mentioned, as lecturer to various institutions, and on several occasions he was chosen to deliver the popular lecture at the annual meeting of the British Association. When he retired from the chair in Glasgow in 1906 the General Council of the University presented to him his portrait, painted by Mr. J. H. Lorimer, R.S.A., together with a sum of £450, which was devoted to the equipment of a laboratory of experimental psychology in the physiology buildings of the University. After his retirement he lived chiefly at Maxieburn, Stonehaven, where he took an active interest in local affairs, and was Provost in 1910. Professor McKendrick, whose wife died

OBITUARY.

JAN. 9, 1926]

in 1898, is survived by two sons and one daughter. One son is a medical practitioner in Glasgow, and the other is superintendent of the Royal College of Physicians' Laboratory at Edinburgh.

Dr. JAMES MURIE, who was, half a century ago, a well known African traveller and explorer, died in the infirmary at Rochford, Essex, on December 21st, 1925, aged 93. He was born at Glasgow in 1832, and was educated at the University in that city, where he graduated as M.D. in 1857, also taking the L.F.P.S.G. in the same year. He went out to Africa soon after he qualified, and there made the acquaintance of Livingstone and Speke. Consul John Petherick was appointed, in 1861, to lead an expedition in support of Speke and Grant, who had started on the journey in the course of which they discovered the source of the Nile, and Murie got the post of medical officer and naturalist on Petherick's staff. This expedition reached Gondokoro just four days too late to relieve Speke and Grant; it lasted over two years, and Murie made important collections of the flora of a country then almost unknown. After returning to England he applied for the post of medical officer with Livingstone's Zambesi expedition, but Dr. (afterwards Sir John) Kirk was chosen. Dr. Murie then settled in London, and became assistant secretary, and afterwards librarian, to the Linnean Society; also lecturer on comparative anatomy at the Middlesex Hospital, and physician to Bethnal House Asylum. St. Andrews University conferred the LL.D. on him in 1877. He was also a Fellow of the Royal Geographical Society, and of the Linnean Societies. Some thirty years ago he retired to Leigh-on-Sea, where he occupied himself in studying the fisheries of the Thames estuary. He was a member of the Kent and Essex Sea Fisheries Committee, and the author of two volumes on the subject. Latterly he had become almost altogether a recluse, and seems to have weakened in intellect, as was not unnatural at his great age. A few days before his death he had a stroke of paralysis, and was removed to the Rochford Workhouse Infirmary for treatment. When his condition became known the South Essex Division of the British Medical Association held a meeting to take steps to look after him, but it was then too late, as he died two days afterwards. Dr. J. F. Walker of Southend attended the funeral service on December 23rd at Leigh-on-Sea Parish Church, as representative of the South Essex Division.

Dr. JOHN PREST WIGHTMAN of Newby, near Scarborough, died on December 19th, 1925, aged 57 years. He studied medicine at St. Bartholomew's Hospital, and took the diplomas of the English Conjoint Board in 1891. He had served as house-surgeon to the Hospital for Children, Myrtle Street, Liverpool, assistant medical officer at the Sanatorium for Consumption, Bournemouth, and as medical officer to the York Dispensary. Some seven years ago he took up practice at Scalby and Newby, in conjunction with Dr. B. G. Forman of West Riding Medico-Chirurgical Society, the York Medical Society, and the Scarborough Division of the British Medical Association. He contributed several papers to the *BRITISH MEDICAL JOURNAL* and other periodicals on enteric fever in childhood, haemophilia, and empyema. Throughout his life he was a keen lawn tennis player, and was very fond of music and singing. He leaves a widow and one son, who is a medical student at Cambridge. At the meeting of the York Medical Society held on December 19th sympathetic reference was made to the loss the society and the profession generally had sustained by his death.

We regret to record the death, on December 1st, 1925, of Dr. JOHN JAGGER PICKLES. He was born in 1851, and received his medical education at Leeds, where he won the gold medal of his year. After obtaining the M.R.C.S. Eng. in 1873, and the L.R.C.P. Edin. and L.M. in 1874, he served as assistant resident medical officer, and later house-physician, to Leeds General Infirmary, and house-surgeon

at the Bradford Infirmary. For fifty years he carried on a large general practice in Leeds, retiring from it three years ago. He was honorary surgeon to the Leeds Tradesmen's Benevolent Society, a steward of the West Riding Medical Charitable Society for many years, and president in 1914. Dr. Pickles was one of the best known practitioners in the city. Of his six sons five became doctors, and all served in the war, two being killed. His wife predeceased him by eight years. A colleague writes that Dr. Pickles was a man for whom everybody had a good word. He was one of a group of medical practitioners who were closely bound together in a long-standing fellowship based upon mutual respect and cordial affection. No cloud of suspicion or misunderstanding was ever allowed to come within their circle. Dr. Pickles was one of the most highly appreciated stewards of the Medical Charitable Society for the West Riding of Yorkshire, a regular attendant at the meetings, and an enthusiastic advocate of its claims on the profession.

We regret to record the death of Dr. REGINALD WOOLSEY Stocks of West Bromwich, which took place on December 19th, 1925. He was the son of the late Dr. Frederick Stocks of Wandsworth, and received his medical education at St. Thomas's Hospital Medical School. He took the diplomas of M.R.C.S., L.R.C.P. Lond. in 1907 and that of D.P.H. Birm. in 1909. After serving as clinical assistant in the ear and throat department of St. Thomas's Hospital, Birmingham, he practised in London for some three years. In 1911 he was appointed deputy medical officer of health and school medical officer at West Bromwich, and two years later, on the death of Dr. Manley, was appointed medical officer of health. He took a keen interest in child welfare and clinic work. During the war Dr. Stocks served first as special sanitary officer to a hospital in India. He was afterwards as surgeon to a hospital in the British Medical Association, and deputy representative (nominated by the public health service members) in the Representative Body at the Annual Meeting at Bath.

Dr. WILLIAM NETTLE of Liskeard, who died on December 23rd, 1925, aged 77, was a native of Liskeard, and received his medical education at St. Bartholomew's Hospital. He took the diplomas of M.R.C.S. and L.S.A. in 1870, and after serving as house-surgeon to the Royal Cornwall Infirmary succeeded to the practice of the late Dr. Alfred Prideaux. For ten years he was a member of the Liskeard Town Council and was mayor on four occasions. He was a borough and county magistrate, was a late lieutenant-colonel in the R.A.M.C., T.F., and held the Volunteer Decoration. He was medical officer of health for the borough and rural district for a long period, but had resigned the latter appointment a fortnight before his death. Dr. Nettle, who was ex-chairman of the East Cornwall Division of the British Medical Association, is survived by his widow and one daughter.

Dr. DAVID RHYS JONES of Cardiff died on December 22nd, 1925. He was born at Ffynnon Wen on September 22nd, 1845, and was educated at the Grammar School, Newcastle Emlyn, and Carmarthen College, and subsequently at University College, London. He took the diploma of L.S.A. in 1875 and that of L.R.F.P.S.Glas. in 1881. After serving as a medical officer of the Three Counties Mental Hospital, Carmarthen, he started practice on his own account in Cardiff in 1889. Two years ago he resigned the post of medical officer and public vaccinator under the Cardiff Board of Guardians, which he had held for twenty-seven years. He took a warm interest in everything appertaining to Wales, and was highly esteemed by all with whom he came in contact.

Dr. DANIEL ALOYSIUS O'SULLIVAN, who died at Bath on December 30th, 1925, aged 82, was educated at the Catholic University, Dublin, where he gained the gold medal in

materia medica, medical jurisprudence, and practical chemistry in 1864. He took the diplomas of L.R.C.S.I. in 1869 and L.R.C.P. Edin. and L.M. in 1873, and subsequently the degree of M.D. (*honoris causa*) was conferred upon him by the National University of Ireland. He had practised in Cork, Burnley, Southport, and London. Dr. O'Sullivan took great interest in the work of the British Medical Association, was a member of the council of the Lancashire and Cheshire Branch for 1897 and 1898, became vice-president of the Branch in 1899 and one of its representatives on the Central Council of the Association in 1900-1, was a co-opted member of the Council for the period 1903-5, and was a member of the Parliamentary Bills Committee in 1901.

Dr. JOHN GOUGH NOLAN of Wigan died suddenly on December 15th, 1925, at the early age of 31. He was a native of Southport, and after receiving his early education at St. Edward's College, Liverpool, proceeded to the University of Manchester, where he graduated M.B., Ch.B., with distinction in surgery, in 1919. In the same year he took the diplomas of the English Conjoint Board. He served as resident medical officer at the Northern Hospital for Women and Children, Manchester, senior house-surgeon and house-physician at the Manchester Royal Infirmary, and assistant medical officer at the Barnes Convalescent Hospital at Cheadle. He subsequently removed to Wigan, and became assistant surgeon to the Wigan police. Dr. Nolan was assistant honorary secretary to the Wigan Division of the British Medical Association.

Dr. AGNES ELIZABETH HENDERSON, who died on December 29th, 1925, was the daughter of the late Sir William Henderson, LL.D., Lord Provost of Aberdeen from 1886 to 1889. She received her medical education at the London School of Medicine for Women, and in Vienna and Brussels, obtaining the diplomas L.R.C.P., L.R.C.S. Edin., and L.F.P.S. Glas. in 1889, and the M.D. Brux. degree in 1890. She was one of the senior medical missionaries of the United Free Church of Scotland, and went out to India in 1890 to work among the women in the Central Provinces, where she was in charge of the hospital at Nagpur. During the war she held an appointment for some time in England as a medical officer to the women and girls in munition factories. She retired from active work in 1922, but continued to live in Nagpur, and devoted her energies to raising funds for the new hospital. She received the M.B.E. in 1923 in recognition of her services to India. She returned to England in the early summer of last year.

Dr. DE-NOS, founder of the Société Internationale d'Urologie and member of the Académie de Médecine, has recently died at Pondicherry while in charge of a medical mission to India.

The Services.

DEATHS IN THE SERVICES.

Lieut.-Colonel James Sullivan Green, R.A.M.C. (ret.), died at Gleanworth, co. Cork, on December 1st, 1925, aged 64. He was educated at Trinity College, Dublin, where he graduated B.A., M.B., and Ch.B. in 1883. He entered the army as surgeon in August, 1885, became lieutenant-colonel after twenty years' service, and retired, on account of ill health, in September, 1916. He served on the north-east frontier of India in the Manipur campaign of 1891, receiving the frontier medal with a clasp; in Burma in 1891-92, with the Travaddy column (clasp); and in the South African war from 1899 to 1902, when he took part in the operations in Natal, including the actions at Elandslaagte, Reibfontein, and Lombard's Kop, and the defence of Ladysmith, and later in operations in the Transvaal, Orange River Colony, and Cape Colony, receiving the Queen's medal with five clasps, and the King's medal with two clasps.

Lieut.-Colonel Bernard Langley Mills, R.A.M.C. (ret.), died at Sheffield on December 28th, 1925, aged 64. He was born at Bishop's Lydeard, Somerset, on June 6th, 1861, and was educated at Edinburgh, where he graduated as M.B. and Ch.B. in 1882, and as M.D. with commendation in 1885. He also studied in Paris, and took the M.R.C.S. in 1892, the F.R.C.S. Ed. in 1896, and the D.P.H. of the Edinburgh Colleges in 1900. He served as surgeon on January 30th, 1886, he after twenty years' service, and retired. After his retirement from the army he got the appointment of medical officer to the education committee, Sheffield. He served

on the north-west frontier of India, in the campaign of 1897-98, on the Malakand, in the operations in Buner, Bajaur, and the Mammund country, and in the attack and capture of the Tanga Pass, receiving the medal with a clasp; and in South Africa in 1900-01, receiving the Queen's medal with five clasps. He also rejoined for service on the outbreak of the recent great war in 1914.

Lieut.-Colonel Maurice Forbes White, Indian Medical Service, died at Bombay on December 4th, 1925, after an operation. He was the youngest son of the late John Forbes White, LL.D., of Aberdeen, and was born on July 9th, 1877. He was educated at the university of that city, where he graduated M.B. and Ch.B. in 1901. He took the D.T.M. at Liverpool in 1910. After filling the posts of assistant house-surgeon of Leicester Infirmary and resident surgeon of the General Dispensary at Birmingham, he entered the I.M.S. in January, 1901, and attained the rank of lieutenant-colonel in July, 1923. He served throughout the recent great war—in Egypt in 1914-15, in France and Belgium in 1915, and with the Egyptian Expeditionary Force in 1916-18; he was twice mentioned in despatches (June, 1918, and June, 1919), and received the French Croix de Guerre (May 15th, 1917) and the O.B.E. (June 3rd, 1919).

Lieut.-Colonel Arthur William Tremblay, Bengal Medical Service (ret.), died at New Milton, Hants, on December 17th, 1925, aged 59. He was born on August 7th, 1866, the son of Frederick Henry Buist of Seane, Perthshire, and was educated at Edinburgh, where he graduated as M.B. and Ch.B. in 1883, and as M.D. thirty years later, in 1919. While a student he assumed the name of Sparks in addition to his own, and entered the service as Buist-Sparks, but dropped the name again in 1898. After filling the post of house-surgeon in the Edinburgh Royal Infirmary he entered the Indian Medical Service on January 31st, 1891, became lieutenant-colonel after twenty years' service, and retired on July 5th, 1921. He went into civil employ in the Punjab in 1893, and remained in that province for the rest of his service, except when delegated to military duty. He served in the Tchi campaign on the north-west frontier of India in 1893, gaining the frontier medal with a clasp, and in the recent great war from September, 1915, to January, 1919, when he was mentioned in despatches in the *London Gazette* of July 4th, 1916.

Universities and Colleges.

UNIVERSITY OF OXFORD.

As examination for the Christopher Welch Scholarship in Biology, 1926, will be held at the University Museum in March next. The scholarship is of the annual value of £100 and will be tenable for four years from the beginning of Michaelmas term, 1926. Candidates must be male undergraduate members of the University who have not exceeded the twelfth term from their matriculation. They may offer any one of the subjects botany, animal physiology, and zoology.

UNIVERSITY OF LONDON.

A MEETING of the Senate was held on December 16th. The following were recognized as teachers of the University in the subjects indicated:

Medical School.—Dr. A. T. Gow (medicine),
Laryngology.
School.—Dr. Anthony Peeling and Dr. Eric
Ham S. Dawson and Dr. Alfred A. W.
Thomas Benton (mental diseases).

The regulations for the second examination for medical degrees for internal and external students were amended by the substitution for lines 26-28 (Red Book, 1925-26, p. 233) and for lines 16-18 (Blue Book, September, 1925, p. 224) of the following words: "A practical examination, not exceeding six hours in length, including:—"

It was decided to instruct the examiners in physiology at the second examination for medical degrees that one optional question in physical chemistry, as applied to physiology, be included in each of the written papers in physiology at this examination.

The following have been constituted Boards of Examiners for the first and second examinations for medical degrees in 1926; the chairman of the respective boards is indicated by an asterisk:

Inorganic Chemistry.—H. J. Evans and *C. S. Gibson, together with the
r. falling him, W. Rushton) and *E. J.
Examiners.
mond, J. A. Hewitt, W. W. Huxley,
C. H. Candy, W. B. Tuck, G. W. Ellis,
*Professor G. S. Gibson,
arley-Smith, W. E. Le Gros Clark,
Wright, Mrs. Lucas Keene, J. E. S.
Frazer, together with the external examiners.
Physiology.—J. P. Hill, R. J. S. McDowall, C. A. L. Evans, J. Mellanby,
G. W. de P. Nicholson, *M. S. Pembrey, H. E. Roaf, Swale Vincent,
J. H. Woodger, B. J.
Pharmacology.—A.
N. Mutch, O. F. F.
B. J. Collingwood, together with the external examiners.

Sir Holburt J. Waring has been elected chairman of the Athletic Appeal Committee.

Essays or dissertations on "The value of the various methods of investigating diseases of the pancreas" intended for the Rogers prize of the value of £100 must be received by the Vice-Chancellor at the University by April 30th. It is open to all persons whose names appear on the *Medical Register*. Further information can be obtained on application to the Academic Registrar.

Medical News.

THE first social evening of the Royal Society of Medicine for 1926 will be held on February 1st, when Dr. F. J. Poynton will give an address on *aerostation and doctors*, a subject in which he has taken special interest for the last twenty years. For the social evening on March 1st Dr. Gustave Monod will come over from Paris to give an address entitled "From Cagliostro to Coué, or Imagination as a Method of Treatment." At the social evening in May Sir Humphry Rolleston, Bt., will mark his translation to the Regius professorship by giving an address on "Some Worthies of the Cambridge Medical School."

A NEW series of post-graduate lectures at the Hospital for Sick Children, Great Ormond Street, W.C.1, will begin on Thursday, January 14th, at 4 p.m. They will be continued on succeeding Thursdays, at the same hour, till April 8th. A series of demonstrations is being given at the hospital on Wednesdays until March 10th.

THE Fellowship of Medicine announces that the Prince of Wales's General Hospital is holding an intensive course from January 11th to 23rd, which will include morning demonstrations of clinical methods, lecture demonstrations of selected cases in the afternoons, and work in the general and special departments of the hospital; lectures at 4.30 p.m. will be given free to members of the North-East London Post-Graduate College and of the Fellowship. The opening lecture will be given by Dr. Eric Pritchard on the principles of nutrition. A series of demonstrations of acute infectious diseases will be given by Dr. Frederic Thomson at the North-Eastern Fever Hospital on Wednesdays at 2.30 p.m. and Saturdays at 11 a.m. from January 13th to 30th. From January 18th to 30th the Queen's Hospital has arranged a special course in diseases of children; morning and afternoon sessions will be held. Also from January 18th to 29th there will be an all-day course in cardiology at the National Hospital for Diseases of the Heart. The opening lecture of the Fellowship's new series will be delivered by Dr. Herbert Spencer on January 21st at 5 p.m. at 11, Chandos Street, W., on abdominal palpation in pregnancy (with lantern demonstration). These lectures are free to medical practitioners. A copy of each syllabus and of the programme of the general course arranged by the Fellowship may be had from the Secretary, 1, Wimpole Street, W.1.

THE annual meeting of the Society of Superintendents of Tuberculosis Institutions will be held at 122, Harley Street, on Monday, January 18th, at 3 p.m. There will be a discussion on occupational therapy, and papers will be read by Dr. J. E. Chapman, Dr. J. R. Lord, Mrs. Kimmins, Dr. Jane Walker, and Dr. Esther Carling. Dr. A. Lucas Hammond will read a paper on phthisical psychology.

AT the meeting of the Medico-Legal Society, at 11, Chandos Street, W., on Tuesday, January 19th, at 8.30 p.m., Drs. Godfrey Carter and Herbert Southgate will open a discussion on the excretion of alcohol in urine as a guide to alcoholic intoxication.

COLONEL R. J. BLACKHAM, C.B., C.M.G., C.I.E., D.S.O., M.D., has been elected a member of the Court of Common Council of the City of London.

DR. C. LEVADITI of the Pasteur Institute, Paris, will give an address on "Recent Advances in the Chemotherapy of Syphilis" at the Dermatological Section of the Royal Society of Medicine on Thursday, January 21st, at 5.30 p.m.

THE sixty-third annual issue of the *City Diary* has a full introductory section, giving particulars of the Corporation of the City of London and a complete record of the Masters, Wardens, and Courts of the Guilds, together with details of every other municipal organization of the City. The diary is published at 2s. by the *City Press*, 148-9, Aldersgate Street.

Revue d'Actinologie is a new French quarterly edited by Drs. E. and H. Biancani, and devoted, as its subtitle indicates, to the study of ultra-violet and infra-red light. The October-December issue contains original articles by Dr. C. Benoit on the physical and physiological properties of infra-red rays, new investigations on rickets by the editors, heliotherapy and the quartz lamp in local tuberculosis by Dr. Armand-Delille, the actinotherapy of endocrine glands by Dr. J. Saidman, and the treatment of generalized acne by ultra-violet rays by Drs. A. Fraikin and A. Buril, as well as reviews and abstracts from current literature.

THE following nominations have recently been made in the Swiss faculties of medicine:—Geneva: Dr. Charles Juillard, extraordinary professor of industrial accidents; Dr. François Naville, lecturer in medical jurisprudence; and Dr. Bujard, extraordinary professor of normal histology and embryology. Lausanne: Dr. Preissig, professor of psychiatry, and Dr. Ramel, professor of dermatology.

DRS. DE LAPERSONNE, Hutinel, Pierre Marie, Chauffard, and Weiss, formerly professors of the Paris Faculty of Medicine, have been nominated honorary professors.

M. MARCHOUX, professor at the Institut Pasteur, has been elected a member of the Académie de Médecine of Paris, in place of the late M. Mesureur of the Assistance Publique.

ON his retirement from the post of medical officer of health for the burgh of Peterhead and also from general practice in the town Dr. Norman Davidson was entertained at dinner by members of the town council and others on December 23rd, 1925, and received a presentation.

A STREET in Brussels near the university has been named after the late Professor A. Depage, and one of the principal streets in Valencia has been renamed after the celebrated histologist, S. Ramón y Cajal.

AN international post-graduate course will be held in Vienna from February 8th to 20th, with special reference to diseases of the digestive organs and disturbances of metabolism, together with their treatment. The course will be followed by practical work in small classes. Applications should be addressed to the Dean, Professor Richard Vasicky, Schlüsselgasse, 22, Vienna VIII, from whom further information may be obtained.

MESSRS. W. HEFFER AND SONS, LTD., Cambridge, hope to publish in February a new (seventh) edition of S. W. Cole's *Practical Physiological Chemistry*. It has been revised and two new chapters on biological oxidations and reductions and on the analysis of blood have been added.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumshough Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

ORAL STENOSIS.

DR. J. HOYTE (Katanga) asks for advice in the following case: Two years ago (he says) a middle-aged native man came for treatment in the camp hospital here. He was suffering from severe tertiary yaws, with extensive ulceration affecting the lips and nose; in fact, these parts were almost completely destroyed and replaced by a dirty sloughing ulcer. Treatment by potassium iodide stopped further spread of the ulceration, and within four or five weeks the healing was complete. Unfortunately the accompanying cicatrization was intense, and resulted in reducing the "mouth" to a small circular orifice, not half an inch in diameter, in the centre of a tough scar. It is difficult to conceive how he talks, eats, and breathes through a hole which will only admit the tip of the little finger! However, he has subsisted for two years now, but is begging me to give him a more sizable sort of mouth. I would be most grateful if some surgeon would tell me of an operation (if any) which could be performed by a non-expert with reasonable hope of success.

We have referred this question to Mr. H. D. Gillies, F.R.C.S., who has been good enough to send us the following reply:

It is difficult to advise in a case such as this without examination or photographic record of the patient. The safest procedure in the circumstances would seem to be as follows:

First Stage.—Starting in the submaxillary triangle of the neck, two parallel incisions are carried down for eight inches over the

clavicle on to the chest. At no portion should the parallel lines be separated by less than two inches. This strap of skin and subcutaneous tissue is raised and sewn with its skin edges together on its posterior surface, making a tube pedicle flap, according to the method I have described in other situations. By suitable undermining the neck skin can be approximated beneath the pedicle flap, which is left attached above and below. Drainage should be provided in the neck.

(Interval of 1 to 2 months, preferably the latter, should be allowed.)

Second Stage.—(a) Division of pedicle from chest. Opening of seam of pedicle enough to cover two-thirds of lower lip. (b) Dense scar tissue excised from lower lip and pedicle sutured into raw area provided on both skin and mucous membrane aspects.

(Interval of 1 month or longer.)

Third Stage.—Division of neck end of pedicle; opening up of the seam; excision of the remaining scar tissue, and pedicle "draped" round new oral aperture.

The excision of scar tissue must be complete.

INCOME TAX.

Partnership; Decease of Partner.

"PUZZLED" writes: A, B, and C were in partnership and made up their accounts to December 31st; in January, 1925, A died and B and C took over the practice, and paid both instalments of the tax payable in 1925—that is, as for the year ended April 5th, 1925. A's executors refunded his share for the first instalment, but demur to refunding more than half of the second instalment, although by far the greater part of the money received up to April 5th was for work done before A's death, for which, of course, A's executors received his share.

* In our opinion the executors are right. "Puzzled" should bear in mind the fact that the tax in question is for the profits of the year 1924-25, not for the cash received in that year. Since A's death all the profits belong to B and C, and they are liable to account for tax accordingly. It is true that in computing the assessment the cash receipts have been taken as the gross income, but this is merely as a matter of convenience and because in the long run the amount of cash received over a period of years should be equal to the value of the professional bookings. Having arrived at an assessment by that means, the question of cash, as distinct from bookings, should be put on one side, and the matter looked at as if the assessment represented the profits or earnings of the practice for the financial year, whether received in cash or still on the books.

Bad and Doubtful Debts.

"G. H. G.'s" firm base their income tax returns on bookings rather than on cash receipts; are they justified in deducting a percentage of the bookings as representing the probable amount of bad debts, and if so, what percentage?

* This is one of the most difficult questions arising on medical practitioners' returns. The legal position is that the practitioner is entitled to a deduction for bad and doubtful debts, but the onus of establishing what is a fair amount rests on him. The final decision lies with the District Commissioners of Taxes, and we understand that in some cases they require evidence in the form of a schedule of outstanding debts setting out the nominal amount and probable value of each debt. However reasonable such a requirement may be in the case of a trader claiming an allowance in respect of a comparatively small number of doubtful debts, it is, we feel, unfair in the case of a medical practitioner whose fees are notoriously not only difficult to collect, but also subject to deductions on grounds which would not carry much weight as regards debts between, say, a manufacturer and his customers. In the circumstances we regard a percentage deduction as a legitimate form of computation. As regards the percentage that should be selected, it is impossible for us to suggest a figure. Bearing in mind that the practitioner can be called upon to defend his claim, and also that it must depend largely on the circumstances of the particular practice, the best suggestion we can offer is that the books for previous years should be examined to ascertain what has, in fact, been the average loss by bad debts, and the percentage so calculated applied to the amount of the book debts outstanding at the close of the period forming the basis of the average.

LETTERS, NOTES, ETC.

ESTIMATION OF SUGAR.

DR. J. BARFR SMITH (London, S.E.) writes: In the *JOURNAL* of November 26th, 1925 (p. 1040), I mentioned a crucible lid for easily ascertaining a glycosuric urine, even when it contains only small quantities of sugar, such as 2 per 1,000, from a droplet of urine. Permit me to say that the Thermal Syndicate, Ltd., make a small

silica disc (No. T/A9/121) for the purposes of my char test, etc. I have always used a silica crucible lid, and the small silica disc should be still more advantageous; its great smoothness, however, has no great advantage. When we realize that so small a quantity as a fiftieth part of a milligram of sugar will be evidenced by the residue char left after washing and rubbing the carbonized droplet of urine, it seems that the char test should be of universal use by medical practitioners, even for quantitative, as well as qualitative, estimation of sugar, both in blood and in urine. The stickiness of the extract, the odour of caramel when discolorization begins, and the adherent residue char, are all characteristic of quantity, and one droplet of urine the size of a large pin's head is sufficient.

RHEUMATOID ARTHRITIS: ITS SEPTIC ORIGIN.

DR. GAVIN A. E. ARGO (Nigbol, Upper Assam) writes: In his note on "Rheumatoid arthritis: its septic origin" (October 24th, 1925, p. 773) Major-General Sir Patrick Hehir states that all classes of Indians wash their mouths after every meal, and infers that by so doing pyorrhoea alveolaris is prevented. In the past few months I have examined the mouths of between 1,200 and 1,300 adult Indians, and approximately 91 per cent. of them have pyorrhoea alveolaris. I have not noted what percentage of these wash their mouths after meals, but am informed it is a more or less general custom. Washing their mouths with water after meals may get rid of a certain amount of food debris, but it is not clear how this custom gets rid of the tartar and pockets, which all these Indians show, and without getting rid of which it is difficult to see how the pyorrhoea is very much benefited.

ECHINOCOCCAL CYSTS IN CAMELS.

IN reply to Dr. J. C. Milne (Hurgada, Egypt), who asked a question about the occurrence of echinococcal cysts in camels (*BRITISH MEDICAL JOURNAL*, December 19th, 1925, p. 1206), Dr. G. W. Sudlow (Stoke-on-Trent) writes: Whilst serving as a temporary officer in the R.A.M.C. I was stationed, in the summer of 1918, in the Kharga Oasis, Libyan Desert. One unit under my charge was a company of Miknir Camel Corps. Their camels were Indian, not Egyptian. After several unaccountable deaths of camels in their lines the Special Service officer attached to them asked me one day to see a sick camel. It was a fine beast, as were they all, apparently in their prime, and much larger and finer than the Egyptian camel. The history was that it had been off its feed for a few days, and was obviously ill and in pain. It died that night, and next day I conducted a *post-mortem* examination—no mean task. I found practically every abdominal organ riddled with cysts, large and small. I sent specimens of liver and kidneys for bacteriological report, which in due course confirmed my diagnosis (*post-mortem*) of hydatid disease. In all I made five or six *post-mortem* examinations on similar cases occurring in their camel lines within a few weeks. In my series of cases I saw both pleural and peritoneal cavities involved by the disease, also lungs, liver, spleen, and kidneys. The Indian officers of the camel corps kept dogs, which had the run of the camp, and the surrounding desert abounded in jackals, so that the source of infection was not far to seek. The camels' fodder was tiffin; this was stacked in the open in the camel lines, and evidently was being urinated upon by the infected dogs and jackals.

THE FIRST LONDONERS.

DR. FERDINAND RHYNS (Southend-on-Sea) writes: If your annotation (December 12th, 1925, p. 1133) correctly represents what Professor Parsons said in his lecture on the prehistoric races, "The Mediterranean race, usually called the Celtic race, were the first race, the round Barrow or Beaker people, intervened between the Iberians and the Celts? I am not disinclined to believe it, but it certainly has not been stressed up to now. Taylor, in *The Origin of the Aryans*, says: "but as there can be little doubt that the people of the round barrows introduced into Britain what is usually called 'Celtic' speech, it will be convenient, though perhaps incorrect, to designate the people of the round barrows as the Celtic race." The question is, were they what we have been accustomed to call Goidels, or did the Goidelic wave of Celts come after them? Professor Rhys does not seem to know anything about these Beaker folk: he only talks of two Celtic waves, the Goidelic and the Brittonic. Professor Parsons is made to say that the Goidels or Gaels were believed to have passed rapidly to Ireland, Scotland, and the Isle of Man, and that the Brittones, reaching this country about 600 B.C., probably called themselves Cymry. But Professor Rhys makes it quite clear that the name Cymry, or Comrades, was only adopted by the Brythons after Cunedda came down from the Northern Wall with his Brythons, who conquered the Goidels who were then in power in the north-west and in a great portion of the south of what is now known as the Principality of Wales. The Princes of Wales always from this time claimed descent from Cunedda Gwledig, or Ruler.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 32, 33, 36, and 37 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 34 and 35.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at pages 19 and 20.

A British Medical Association Lecture ON INSULIN TREATMENT OF DIABETES:

WITH PARTICULAR REFERENCE TO
THE COMPLICATIONS OF DIABETES AND TO SURGERY
IN DIABETICS.*

BY

J. A. NIXON, C.M.G., M.D., F.R.C.P.,

PROFESSOR OF MEDICINE IN THE UNIVERSITY OF BRISTOL; SENIOR
PHYSICIAN TO THE BRISTOL ROYAL INFIRMARY; CONSULTING
PHYSICIAN TO SOUTHMEAD HOSPITAL, BRISTOL.

The death of a diabetic patient is never strictly a death from diabetes; it is a death due to some preventable complication of diabetes or to an intercurrent disease. Diabetics certainly die of pneumonia, tuberculosis, cancer, nephritis, apoplexy, and even of old age, and it is true that their resistance to any disease is lessened. Yet the main causes of death in diabetes down to the present time have been coma and gangrene.

How frequently coma is accountable for the fatal ending in diabetes can be realized from the figures given by Joslin¹ from his own clinic, where 66 per cent. of the deaths down to 1915 were due to coma, and from von Noorden's clinic, where the figure was 58 per cent. Von Noorden and Joslin show by their statistics how much more common coma is in young than in older diabetics. Fitz and Murphy,² in their analysis of the causes of death in diabetes, demonstrate that death from coma without some complicating infection is relatively rare at any age. Joslin has observed that nearly all diabetics who die in the first year of their disease die of coma. The explanation of this appears to be that on the discovery of the disease there is a great risk that the diet will be suddenly changed. If carbohydrates are restricted while protein and fat are simultaneously increased, coma may ensue forthwith.

Infections and an ill balanced diet constitute the chief dangers, therefore, of diabetes. The dangers of a diet containing an excessive proportion of fat are not even now sufficiently recognized. Since the introduction of insulin coma has become avoidable in practically every case. Infections more than anything else are responsible for serious diminution of carbohydrate tolerance in diabetes. These infections may be classified under two headings—general and local.

GENERAL INFECTIONS.

Pneumonia was responsible for 52 out of 887 deaths in Joslin's series, yet diabetics do not all die when they develop pneumonia—there were 13 recoveries. Influenza appears very fatal amongst diabetics when it comes in epidemic or pandemic form; sporadic cases stand a better chance of recovery. Tonsillitis, whooping-cough, dysentery, and erysipelas are dangerous complications; but diabetics may pass unscathed through measles, mumps, scarlet fever, varicella, and even whooping-cough. It is interesting to note that acute rheumatism very rarely attacks a diabetic patient.

Tuberculosis deserves more particular attention. Banting³ has said that tuberculosis in diabetics usually progresses rapidly and ends fatally. This is not invariably the case; not infrequently the phthisical diabetic will live many years as a chronic invalid. Diabetes may sometimes disappear when tuberculosis intervenes. The intervention is often insidious. Pyrexia is characteristically absent, hæmoptysis is rare, so that any loss of weight can be mistakenly attributed to diabetes. I have been surprised occasionally to find in chronic diabetics extensive signs of pulmonary tuberculosis which had been unsuspected. Suspicion of tuberculosis should be aroused whenever an unexplained improvement of carbohydrate tolerance is seen in diabetes. Allen suggests a reason for this increased tolerance, in that fasting and loss of weight will improve

the tolerance of the severest diabetic patients. The advent of insulin enables us to feed tuberculous patients with adequate diets, so that the diabetic consumptive is now no worse off than the non-diabetic in respect of nourishment.

LOCAL INFECTIONS.

Local infections are really more important than general. Septicæmia is a commoner cause of death, for example, than pneumonia. Joslin gave 6.9 as the percentage death rate from pneumonia of his fatal cases of diabetes; the figure for the general population of Massachusetts was 6 per cent. of the total deaths.

Other important local infections are boils, carbuncles, and gangrene. It may cause surprise to find gangrene mentioned among the local infections. The form of gangrene seen in diabetes is not as a rule the sudden complete blocking of a large vessel. When this occurs, as it does occasionally, the patient generally shows advanced arterio-sclerosis, and the case should be regarded as senile rather than diabetic gangrene. Such a patient may not survive amputation because of diabetes; thus diabetes may contribute to his death. But true diabetic gangrene is commonly caused by some local infection to which the soft tissues respond by a rapidly spreading necrosis. Comparatively slight injuries may lead to severe gangrene. Without insulin surgical intervention may do no good; with insulin treatment it may prove unnecessary; if insulin alone is not sufficient to check the progress of the gangrene it will contribute wonderfully to the success of an operation. Joslin⁴ considers that the majority of cases of gangrene are due to injuries occurring to unclean feet, and he has therefore laid down an almost surgical drill for the care of diabetic feet.

Boils and carbuncles are important examples of local infection; they will be considered later with other skin complications.

Many local infections present grave problems when they complicate diabetes, although they may not result even indirectly from diabetes. Gall stones, cholecystitis, and pericholecystitis may be suspected of being in some instances the precursors or exciting causes of diabetes. Seeing that we are often called upon to consider their treatment after diabetes has been established for some time, in practice they become complications. No one should hesitate to operate in such cases on account of the diabetes. Operation may distinctly improve the state of the pancreas. The patient should, if possible, be given a preparatory course of insulin; it need not be long—two or three weeks are often sufficient to bring the blood sugar to normal, to restore the patient to an adequate carbohydrate diet, and to repair his nutrition.

Appendicitis and perinephric abscess may be so acute as to permit of no delay for preparatory insulin. In such cases large doses of insulin accompanied by glucose should be started at once, before or after the operation. Coma and suppuration are very grave dangers in these urgent operations. As an illustration of the dosage I may quote the case of a diabetic woman of 73 who underwent an urgent operation for gangrenous appendicitis. Before the operation she was living comfortably on 20 units of insulin (divided into two doses) daily. After the operation the insulin was increased to 20 units four times in the day. This dosage kept the urine sugar-free, but her blood sugar three hours after a feed was as high as 222 mg. per 100 c.c.m. of blood. During convalescence the insulin was reduced to 15 units twice a day.

Dental abscesses and pyorrhœa are chiefly dangerous by lowering the carbohydrate tolerance, and as such need treatment. In diabetics all bad teeth should be removed, and all pockets of pus must be cleared out. Without insulin, general anaesthesia brings the risk of coma, and infiltration of the gum with local anaesthetics may give rise to sloughing.

NON-INFECTIVE COMPLICATIONS.

Among complications other than the infections arterio-sclerosis takes an important place, especially in protracted cases. It seldom occurs in young diabetics, and when it does it should lead to a suspicion that congenital syphilis

*Delivered at a meeting of the North Lancashire and South Westmorland Branch at Calgarth, Windermere, on December 5th, 1925.

INSULIN TREATMENT OF DIABETES.

JAN. 16, 1926]

diabetes, and such patients show a terrible proneness to a low form of erysipelas and cellulitis." That was a true picture of pre-insulin surgery, but now it need never be seen. As Lawrence³ says, "with insulin to aid us operations can be undertaken with practically the same safety as in normal individuals." In general, minimal operative intervention is indicated in diabetic patients, yet it must be radical enough in gangrene and infection to rid the patient of a focus likely to diminish carbohydrate tolerance. Surgeons and physicians sometimes delay surgical procedures in diabetes which in non-diabetic patients would be resorted to early and with favourable results. Yet early recognition of surgical complications, acute appendicitis, suppurative cholecystitis, pelvic suppuration, strangulated hernia, and, above all, gangrene, brook less delay than in normal individuals. Joslin⁴ has remarked that the complaints of diabetes to-day are one-quarter surgical, and if surgical delays are dangerous in ordinary circumstances, in diabetes they are disastrous.

The two principal dangers of operation are coma and sepsis. Both these dangers can be done away with if insulin is administered adequately and persistently. Many diabetics do not require insulin while in their usual health; dieting alone suffices for them, but when any operation becomes necessary insulin may be urgently needed to render them fit for it. After operation they may be able to dispense with further insulin and resort to simple dietetic measures once more. It is not the case that when a patient begins insulin it must be continued during the whole of a lifetime. A sufficient degree of carbohydrate tolerance may be re-established by the very operation which rendered insulin temporarily needful. Operation cases are of two sorts—emergencies without time for preparatory insulin, and deliberate operations which allow time for preparation with insulin.

In emergency operations, where glycosuria is present without acetone or diacetic acid, 20 units of insulin may be injected before the anaesthetic is begun. It may be objected that there is danger in administering insulin without first determining the history of thirst, polyuria, and either obesity or emaciation, will distinguish the case from one of renal glycosuria with a low blood sugar. The probabilities of encountering renal glycosuria are not actually great. Moreover, glucose should always be at hand for oral, rectal, or intravenous administration in any event, since there is a chance that the dose of insulin given to a patient without previous blood sugar estimation will prove too large and produce symptoms of hypoglycaemia. This possibility would never deter me from giving insulin before an emergency operation. Hypoglycaemia is a less evil than an operation on a diabetic without insulin. As soon as possible the blood sugar should be estimated in order to regulate subsequent dosage. During after-treatment my practice is to tell the surgeon to order glucose rectally or in any other way he thinks advisable, just as though the patient had not diabetes. I then give insulin before each administration of glucose in the proportion of one unit of insulin for each gram of glucose ordered. If it is found that the blood sugar is high I add extra insulin; but as the case progresses I am careful to watch that the blood sugar does not fall below normal. It is carbohydrate that the post-operative case of diabetes needs; I give insulin so that the carbohydrate may be utilized, checking the intake of carbohydrate and the blood sugar in order to ensure that the patient is profiting by the carbohydrate. This, I believe, is the secret of making surgery safe for diabetics.

If there is time for deliberate preparation before operation, the blood sugar should be determined and the patient placed on an adequate diet *plus* insulin. There must be no attempt to prepare a diabetic for operation by starvation or undernutrition. This is inviting disaster. If on an adequate diet the patient's blood sugar is not at a safe level insulin sufficient for an adequate diet must be given forthwith. Further, a patient about to undergo an operation demands something above a barely adequate diet, particularly in its carbohydrate content. There are at least three reasons for raising the diet beyond the minimal

requirements: first, the condition which is making the operation necessary; secondly, the effect of the operation as regards shock; and thirdly, the anaesthetic.

ANAESTHESIA.

Anaesthetics by themselves constitute a grave peril to diabetics. For some reason at present not fully explained anaesthesia produces a rise in blood sugar, and it is an old experience that anaesthetics predispose to diabetic coma. Chloroform is the worst in this direction, and next comes ether. Gas and oxygen seems the least dangerous, but it is by no means invariably safe. Local anaesthesia is not devoid of risks. In dental practice, as in ordinary surgery, infiltration anaesthesia may lead to destruction of tissues with extensive necrosis and sloughing. Spinal anaesthesia may be followed by coma just as anaesthesia by inhalation. Dr. A. L. Flemming, my colleague and anaesthetist to the Bristol Royal Infirmary, long ago insisted on the fact that starvation before an operation could produce acetonaemia in non-diabetic patients; *a fortiori* starvation must be forbidden in preparing a diabetic for an anaesthetic. There is, in fact, no anaesthetic which is safe for a diabetic until he has been enabled to take an adequate amount of carbohydrate in his diet. For it must be always borne in mind that it is sugar that protects the diabetic, and insulin only renders the blood sugar utilizable.

PREGNANCY.

The subject of pregnancy and diabetes demands a few words. Whilst glycosuria without high blood sugar is common in pregnancy true diabetes is uncommon. Therefore a diagnosis of diabetes should not be made in pregnancy without blood sugar estimation. In the rare instances where a diabetic woman becomes pregnant or diabetes supervenes during pregnancy the prognosis is usually more serious for the foetus than for the mother. Premature labour takes place in nearly half the cases. Hydramnios is of common occurrence; the foetus may be enormous—overnourished apparently by the rich content of sugar in the maternal blood. It seems⁵ that the foetal pancreas is practically never deficient, and some observers go so far as to declare that the foetal pancreas helps the mother, so that occasionally the diabetes improves during pregnancy. But it is very rare for pregnancy to exert a permanently favourable influence on a diabetic mother. It rather tends to aggravate the disease. Now, since the introduction of insulin diabetic women are becoming more fertile, and with adequate diet and insulin the pregnancy and confinement may be passed through uneventfully by both mother and foetus. It is imperative to keep a close watch on the mother's blood sugar, nutrition, and, more than all, to be on the look-out for acidosis or acetonaemia. Hepatic insufficiency is a danger even for the non-diabetic mother; it is still more to be feared in diabetes. The coma of eclampsia and diabetes may be difficult to distinguish. The same kind of precautions will guard against each. During pregnancy a diabetic woman may require an increased dosage of insulin; during the puerperium it may be even more essential. Puerperal infections, however slight, will certainly diminish carbohydrate tolerance, and the general principles which apply to surgery must be even more clearly observed. Lactation calls for exceptional nourishment of the mother; her diet will need to be increased, and with it the dose of insulin.

INSULIN ADMINISTRATION.

This subject can only be briefly touched upon. When a case of true diabetes develops a serious complication or intercurrent disease, or when a surgical operation becomes necessary, the last thing that must be thought of is treatment by fasting or the slightest degree of undernutrition. The patient must receive a diet which contains an adequate amount of protein and calories. A useful gram of protein and 35 calories per kilogram of body weight. Several ways of determining these requirements have been suggested, but nearly all of them are based either on the body surface or weight of the patient as he is. In my opinion there is a risk of underestimating the real requirements by

weighing or measuring an unduly wasted body. I prefer to reckon how much the patient ought to weigh if in good health; for this purpose age, height, sex, and the general tendency of the patient's family should be taken into consideration. Having decided on this basis approximately how much the patient should weigh, I prescribe a diet which shall contain 1 gram of protein and 35 calories per kilogram of the assumed weight.

I use Woodruff's formula for the proportions of protein, fat, and carbohydrate—namely, that the fat in the diet shall be equal to twice the carbohydrate plus half the protein. On this formula the minimal diet for a weight of 50 kilos (or 110 lb.) is: fat 139 grams, carbohydrate 57 grams, and protein 50 grams. It is advisable to start immediately with the full adequate diet; there is no time when infection is present or an operation is about to be performed to commence with diets of the "ladder" type. The patient must be well fed from the start, and sufficient insulin must be given to keep the blood sugar at a safe level. It is not a bare subsistence the patient requires, but an allowance (of carbohydrate at any rate) which would nourish him if in good health and give a reasonable margin for combating the infection or facing the shock of an operation. I have already described how, in the after-treatment of operation cases, the surgeon is permitted to give the patient as much glucose, and in such a manner, as he would do if the patient were non-diabetic. Subsequently, as the surgeon modifies the diet, the insulin is adjusted to keep pace with it. But there must be no diminution of carbohydrate because the patient is diabetic. The insulin must be pushed in surgical emergencies as fearlessly as in the dreaded emergency of coma. For the treatment of coma the method recommended by Campbell¹² should be followed.

"Patients in diabetic coma who have not received treatment require larger doses of insulin. As speed is essential and the rate of action of insulin is only doubled by taking ten times the dose, we commonly use 100 units of insulin intravenously as the initial dose. Most of the coma patients are dehydrated and fluid must be supplied liberally. Some of this may be given intravenously as 10 per cent. glucose solution, at a rate not greater than 10 c.c.m. per minute. If the pulse rises ten beats per minute, discontinue the injection. Normal saline or 5 per cent. glucose may be injected interstitially and given per rectum by the Murphy drip method after a cleansing enema has been given. Many patients difficult to rouse will respond by automatic swallowing movements when a teaspoonful of fluid is poured into the mouth. Except by direct injection into the circulation it is doubtful if too much fluid can ever be administered to a diabetic in coma. Warmth must, of course, be provided. The room should be warm and warm blankets and hot-water bottles used. Circulatory stimulants should be begun early, digitalis and coffee by mouth or per rectum being the most satisfactory stimulants, pituitin and ether being used for more acute emergencies. In my opinion alkalis in moderate doses, 15 to 20 grams NaHCO_3 , are of value when administered by mouth or per rectum in 5 per cent. solution. The intravenous injection of sodium bicarbonate solution is to be employed with caution as it may induce cardiac dilatation and failure. Hypoglycaemia must be avoided and carbohydrate must be available to replace the defective fat metabolism as well as to burn up the ketones already produced. This is provided by giving the patient approximately 1 gram of sugar for each unit of insulin. The use of a retention catheter and testing the urine for sugar each hour will give ample warning of a deficiency of available carbohydrate."

THE TRANSMISSION OF BLOOD SAMPLES.

I have been asked how blood may be sent by post for purposes of blood sugar estimation. The following plan is one that I have found useful and effectual. With a hypodermic syringe withdraw 1 c.c.m. of blood and empty it into a small glass tube (such as is used in laboratories for precipitation tests. Widal, Wassermann, etc.) containing a few crystals of neutral potassium oxalate. Shake the blood thoroughly to mix it with the oxalate and prevent clotting. Wash the hypodermic syringe well with plain water and then absolute alcohol. Draw up into the syringe exactly 0.2 c.c.m. (or 5 minims) of oxalated blood, then fill the syringe exactly to the 1 c.c.m. mark (or to the 20 minim mark) with absolute alcohol. Shake well and empty the contents of the syringe into a second small glass tube. Cork tightly and dispatch, properly packed, by post. The mixture of oxalated blood and alcohol will contain a 1 in 5

solution if the syringe was graduated in cubic centimetres, and a 1 in 4 solution if graduated in minims. The blood sugar can be estimated accurately from the alcoholic solution.

NOVASUROL AND OTHER DIURETICS IN CARDIAC OEDEMA.

BY

C. G. LAMBIE, M.C., F.R.C.P. (Ed.).

ASSISTANT PHYSICIAN, ROYAL INFIRMARY, EDINBURGH; LECTURER IN CLINICAL MEDICINE, UNIVERSITY OF EDINBURGH.

THE value of mercury as a diuretic in the treatment of cardiac dropsy has long been recognized, the drug being usually prescribed along with digitalis, as in Guy's pill. The combination of digitalis with mercury was so much the rule that some doubt existed as to whether mercury possessed any diuretic action independent of its association with digitalis. This point may be said to have been settled, as mercury in the form of metallic mercury (pil. hydrarg.), for example, will increase the elimination of urine in cardiac dropsy apart from the administration of digitalis, though the diuresis may not be so marked as when the latter is given as well. The appearance, therefore, of an organic compound containing a large percentage of mercury, capable of being injected intramuscularly or intravenously, and exhibiting powerful diuretic properties, is of interest.

Novasurol has been studied in America and in Germany, but, save for a recent article by Dr. A. R. Gilchrist of Edinburgh, observations upon its clinical use do not seem to have been reported in this country. It contains 33.9 per cent. of mercury, and the dose is 1 c.c.m. of a 10 per cent. solution. The amount of mercury, therefore, in one dose is comparatively small—only 0.0339 gram, or about that contained in $1\frac{1}{2}$ grains of pil. hydrarg.; nevertheless, the diuretic action is much more pronounced than in the case of metallic mercury administered in the usual way by the mouth. As the mercury in novasurol is not in an easily ionizable form, it possesses a low toxicity and is non-irritating locally, provided that none escapes into the subcutaneous tissues. Moreover, gripping and a tendency to diarrhoea—drawbacks attendant upon the oral administration of mercury—are obviated. The solubility of the drug, permitting of its rapid absorption from the site of injection, probably favours a more intense and rapid action than that exhibited by metallic mercury or calomel.

CASE I.

This case appeared to be peculiarly suitable for the study of various diuretics. The cardiac failure was progressive, little influenced by digitalis and not complicated by any abnormal rhythm. A record of the output of urine over a period of 109 days, during which different diuretics were administered (see graph), shows that novasurol was capable of causing a profuse diuresis when all other diuretics, including metallic mercury, had failed. The patient was a man, aged 68, suffering from syphilitic aortitis, with aortic and mitral incompetence and oedema of the legs, together with some ascites. The urine contained traces of albumin, while the blood urea nitrogen was 22 mg. per cent., and the blood chlorides 450 mg. per cent., showing that there was no evidence of chronic nephritis. He was put on a light dry diet and the intake of water was kept approximately constant. During the first week no drugs were given and the effect of rest in bed was observed. Then tincture of digitalis $\text{m} \times \text{i} \times \text{i}$ was administered, and no increase in the urine was noted. On the twentieth day caffeine gr. iij $\text{i} \times \text{i}$ was added, but little if any change in the output of urine followed. The digitalis and caffeine were then discontinued and urea in large doses, 15 grams three daily, was given over a period of five days, when the volume of urine increased from 600 up to 2,500 c.c.m., after which it gradually returned to the previous level. When the output had decreased to about 400 c.c.m., digitalis and

being 180 seconds. Conjunctival anaesthesia under borocaine usually lasted well over five minutes with the 2 per cent. solution, and over ten minutes with the 4 per cent. solution. With cocaine anaesthesia the conjunctiva was always insensitive for at least five minutes.

After-effects.—To test the after-effects the anaesthesia was induced with 5 per cent. cocaine and with 4 per cent. borocaine, and the eye was inspected the next day. Borocaine was used in 31 cases and 16 returned. Cocaine was employed in 31 cases and 18 returned. The accompanying tables record the results, and so far as they go point to cocaine, even in 5 per cent. solution, as being less harmful to the corneal epithelium than borocaine. Removal of a foreign body appears to be more likely to be complete in the case of cocaine than in that of borocaine. The effect upon the tension is shown in Table III (some of the cases tested had glaucoma). It would appear that the effect of the two drugs is much the same, but borocaine appeared to cause a rise of tension in a greater number of cases than cocaine.

TABLE I.—5 per cent. Cocaine.

Subjective Condition.	Condition of Conjunctival Vessels.	Condition at Site of Removal.
Irritable	Injected	Irregular peeling of surface epithelium.

29	63	" 2%	20.5	21	No.
30	32	" 2%	16	14	No.

The conclusion of the two authors is that borocaine is greatly inferior to cocaine as regards its surface anaesthetic effect. Cocaine is perfectly reliable, whereas the effect of borocaine is variable.

The cost of borocaine makes it an impossible drug for hospital use, the more so as it appears to have no advantages.

THE CLINICAL USE OF BOROCAINE BORATE AND BETA-EUCAINE BORATE FOR URETHRAL ANAESTHESIA.

BY

RALPH COYTE, M.B.LOND., F.R.C.S.ENG.,

ASSISTANT SURGEON TO ALL SAINTS' HOSPITAL AND THE QUEEN'S
HOSPITAL FOR CHILDREN.

BOROCAINE borate and beta-eucaine borate have both been used at All Saints' Hospital for Genito-Urinary Diseases to provide urethral anaesthesia before the passage of various instruments. In the cases here remarked two injections of half an ounce were given at an interval of five minutes. After waiting for three minutes the selected instrument was passed.

BOROCAINE BORATE.

In two cases 0.5 per cent. solution was used; in both of these 0.5 solution of cocaine hydrochloride was used as a local anaesthetic at previous instrumentation. The first case was for the passage of a cystoscope, and the second for a No. 20 French gum-elastic bougie. These two patients

reported that anaesthesia was not quite so good as it had previously been with the cocaine solution.

In 5 cases, all of whom had been previously anaesthetized with 0.5 solution of cocaine, 1 per cent. solution was used. In the first it was for the passage of a Kollmann's dilator, and in the second of a cystoscope; the remaining three were cases of gonorrhoea in which silver nitrate solution was being instilled into the posterior urethra. All the patients reported that borocaine gave them better anaesthesia than the 0.5 per cent. solution of cocaine.

In 3 cases 2 per cent. solution was used before the passage of a Kollmann's dilator. All these patients had had frequent previous injections of cocaine. It was also used for two cases of cystoscopy where there was no history of previous instrumentation. In the first three of these cases the patients reported perfect anaesthesia and relaxation was improved, as evidenced by the fact that dilatation was higher than usual. In the two cases of cystoscopy anaesthesia and relaxation were perfect, and I consider decidedly better than it would have been with a 0.5 per cent. solution of cocaine. A 5 per cent. solution was tried in the three cases of urethral stricture, with perfect results as far as anaesthesia and relaxation were concerned, but really there was no advantage over the 2 per cent. solution. One of these three patients complained for about two or three minutes of a feeling which he described as rather like a lump in the throat, but this passed off, and there were no further symptoms.

In two cases 2 per cent. solution of norocaine hydrochloride was used as a control. These patients had both had frequent injections of 0.5 per cent. solution of cocaine hydrochloride for the passage of a Kollmann's dilator. They reported that anaesthesia was not so good as before, and relaxation was less, in that dilatation fell short of the point reached on previous occasions.

Conclusions.

A 2 per cent. solution of borocaine borate was a considerable improvement over 0.5 per cent. solution of cocaine in respect both of anaesthesia and relaxation, and there was no sign of toxicity.

The 2 per cent. solution of norocaine hydrochloride fell short of a 0.5 per cent. solution of cocaine. A 1 per cent. solution of borocaine borate gives better anaesthesia than a 0.5 per cent. solution of cocaine.

A 0.5 per cent. solution of borocaine borate has no advantage over a 0.3 per cent. solution of cocaine.

The cocaine solution used at All Saints' Hospital is made up with 0.5 per cent. sodium bicarbonate and 1 in 40 camphor water. A 1 per cent. solution of cocaine has not been tried owing to the risk of toxicity.

BETA-EUCAIN BORATE.

This was used on patients who had previously had frequent injections of 1/2 per cent. cocaine hydrochloride solution. The following results were obtained.

Beta-Eucaine Borate 1/2 per cent.—This was used in two cases for dilatation of urethral stricture with a Kollmann's dilator. Both patients reported that they had never had such perfect anaesthesia, and relaxation was also very good.

Beta-Eucaine Borate 1/4 per cent.—This was used in two cases of urethral stricture before the passage of a Kollmann's dilator. Both patients reported that they saw no difference between this and their previous injection, and relaxation was the same.

Beta-Eucaine Borate 1/8 per cent.—This was used in two cases of urethral stricture, for the passage of a Kollmann's dilator in one case and a gum-elastic bougie in the other. Both patients reported rather more pain than they usually got with 1/2 per cent. cocaine.

Conclusions.

Beta-eucaine borate in 1/2 per cent. solution is a perfect urethral anaesthetic, and relaxation is also perfect. In 1/4 per cent. solution it is equal in its action to 1/2 per cent. cocaine hydrochloride. In 1/8 per cent. solution it is not so good as 1/2 per cent. cocaine.

A 1 per cent. solution of this borate was not used owing to the perfect result of the 1/2 per cent. solution.

THREE CASES OF MIDDLE-EAR DISEASE WITH INTRACRANIAL COMPLICATIONS.

BY

H. MORTIMER WHARRY, F.R.C.S.ENG.,

ASSISTANT AURAL SURGEON TO THE BOLINGBROKE HOSPITAL; LARYNGOLOGIST TO THE WEST END HOSPITAL FOR NERVOUS DISEASES; AND ASSISTANT TO THE THROAT AND EAR DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL.

It often happens that patients who have suffered from chronic suppurative otitis media imagine themselves to be cured because all discharge from the ear has practically ceased. They then return to their normal way of life, giving their condition no further thought; so that one or two striking instances of the risks so run may not be out of place. Instead of keeping their ears under the occasional observation of an aurist, they lull themselves into a state of false security until some disaster occurs and they are found to be in imminent danger of death, when nothing but prompt and drastic surgical intervention can save them. A typical pathological condition under which this occurs is cholesteatoma formation. Under local conservative treatment of the nose and ear all discharge ceases; but the irritation of infective matter still remaining in the attic or antral regions causes proliferation of epithelium, until an amorphous cheesy mass is formed in which cholesterol crystals are thickly deposited. Gradually the bone becomes eaten away until the dura mater is exposed, when the invasion of lateral sinus or brain is only a matter of time.

An ear which is dry but foul-smelling should always be suspect, and if a few fibres of cotton-wool twisted closely on a carrier are introduced through the perforation (often in the attic region) and come away coated with thick nauseous matter the diagnosis of cholesteatoma formation may be made with confidence and a radical mastoid operation advised. Unfortunately, as discharge ceases, patients often take matters into their own hands and disappear; but they should previously be warned that the ear requires occasional supervision, unless it is so obviously healthy that the patient can be dismissed with a clear conscience on the part of the aurist. Every aurist knows of cases where patients have neglected or have failed to understand such advice and paid the penalty of death. In the cases I have selected the patients were somewhat more fortunate; each case presents certain individual features which are interesting of themselves apart from any moral to be drawn therefrom.

CASE 1.—Cerebellar Abscess with some Unusual Features.

A young agricultural labourer had for some weeks been suffering from bad headaches, and after a short time became increasingly drowsy. He was accordingly admitted to the Romford Infirmary under Dr. O'Loughlin.

After an initial rise of temperature lasting three days the fever subsided and the body heat became if anything subnormal and remained so. The pulse also after a short period of increased rate became normal and of good quality. Meanwhile the mental condition progressively deteriorated and the patient was almost continuously in a state of coma, from which he could with difficulty be aroused to take a little food at intervals. He gradually lost weight and became very emaciated. His limbs were flaccid and no definite reflex responses could be obtained. There was a vague history of his having, some years previously, suffered from middle-ear disease, but there was now no discharge from either ear and he had for a long time been considered cured of that trouble. The condition seemed to warrant a diagnosis of encephalitis lethargica, and after a second concurring opinion the patient was treated from this point of view.

He gradually became worse, could no longer be roused from coma, and on Saturday night, August 30th, 1921, profuse discharge started from the left ear and a little from the right ear; the next day I was called to see him.

Examination showed the patient to be in the last stages of emaciation—resembling a case of cholera. All the bony prominences of his face were clearly defined, with deep hollows between them. He was quite unconscious and his mouth lay open, with sordes on both lips and tongue. He had lost his left eye in infancy, but the right was half closed, with the pupil turned upwards. All his limbs were flaccid and his knee-jerks absent, while Babinski's and König's signs were negative. The pulse (76) was of good volume and pressure; the temperature was subnormal; the respirations were only four to the minute, and the patient appeared to be moribund.

A diagnosis of left-sided intracranial abscess was made owing to the profuse discharge from the left ear, and an immediate

operation decided upon as the only chance of saving his life. Within half an hour he was on the table, and was given an anaesthetic of open ether in the hope of stimulating his respirations; this was successful.

Operation.—A rather wide post-auricular incision was made and the mastoid process opened. Pus was soon found, and, a little deeper, a cholesteatoma; there was an "overhanging" middle fossa and a "forward" lateral sinus. A considerable area of dura mater was rapidly exposed over both middle and posterior cranial fossae; everywhere the temporal lobe and cerebellum bulged into the field of operation under high pressure; the whole area was in a state of intense engorgement and of soft consistency, it being impossible to distinguish brain from dura mater. On gently probing the soft red mass in the direction of the cerebellum, pus was seen to come from a posterior direction, and a director was passed into a large abscess cavity backwards and inwards. The pus, which was liquid and foul-smelling, was allowed to escape slowly while the radical mastoid operation was completed with some difficulty owing to the bulging of the brain into the cavity. Pus escaped slowly for about half an hour, and I estimated it at 1 to 1½ ounces. The director passed into the cavity for 2 inches, but the width of this cavity was impossible to estimate owing to the surrounding encephalitis and high pressure, which was so great that a small-bore rubber drainage tube passed into the bottom of the cavity was squeezed out again in two or three seconds, and had to be transfixed by a safety pin and held in position by the dressings. The pinna was then packed forward, dressings applied, and the patient returned to bed.

The respirations had by this time become fifteen to the minute, due to the relief of intracranial pressure on the respiratory centre in the medulla oblongata following on the evacuation of the abscess.

Progress.—The course of events was then as follows: Two days later the patient regained consciousness. The tube was replaced

CASE II.—Lateral Sinus Suppuration with Metastases in Lung and Shoulder.

A young man, aged 20, was admitted to University College Hospital complaining of headache. His temperature was raised and his pulse rapid, and it was thought that he had influenza. A year previously he had attended the hospital for a running ear, but believed himself to have been cured of that complaint as all discharge had ceased, and he discontinued coming.

Two days after admission he had a rigor, and his right ear became tender on pressure over the mastoid process; I then saw the case and made a diagnosis of lateral sinus thrombosis. The membrana tympani had a small perforation behind the handle of the malleus, was not inflamed, and only a little moist. An operation was performed without delay.

Operations.—The usual curved post-aural incision was made, and the mastoid opened. The cortex was thick and very dense, but pus was soon found in a large cavity, involving the atrium and the cells adjacent to its lower border, the greater part of which was occupied by a cholesteatoma. A radical mastoid operation was completed, during which the facial nerve, laid bare by the cholesteatoma, was unfortunately cut. A channel of soft bone was then found running through the dense cortex and was exposed until the lateral sinus was laid bare. As soon as a small piece of bone was removed from over it pus welled out and the sinus wall was seen to be collapsed. Accordingly the ear wound was temporarily covered with dressings, and the jugular vein was exposed in the neck. The common facial vein was divided between ligatures, and 1½ inches below its junction the jugular vein was divided between ligatures and the upper end brought out on to the neck through the upper part of the incision, which was otherwise closed. Dressings were applied and the mastoid wound was again investigated. More bone was removed from the sinus, and the outer wall of its dura mater, which usually lies in contact with the bone, was found partly destroyed and its remains rolled up

Temperature chart of Case II, showing the various stages of the patient's illness.

every day for a week, when it could no longer be introduced. The skin flap was allowed to fall back into place. The mental condition remained poor.

Three weeks later, when I again examined the patient, it was found that the wound had nearly healed and that there was no longer any discharge from the meatus. The right eye showed coarse nystagmus to the opposite side. There was some weakness of grip of the left hand compared with the right, and he had difficulty in pronating and supinating rapidly the clenched fists of both hands at the same time in a symmetrical manner, the difficulty taking place in the hand on the same side as the cerebellar lesion—a condition called dysidiadokokinesis; he also had some difficulty in carrying food to his mouth with the left hand. The knee-jerks were absent; Babinski's sign indefinite. His general condition was much improved; he had put on flesh and could take food well. His mental condition was poor, but he could ask for what he wanted.

During the next three months he put on 3 st. in weight, and then went back to his work as an agricultural labourer. His only inconvenience during convalescence was some inco-ordination of the left leg. His mental condition remained poor, but, on the other hand, he had never at any time shown any intelligence above a low bucolic level. He finds no difficulty in doing his work.

My thanks are due to Dr. O'Loughlin for the opportunity of operating on this case, and for himself successfully carrying out the after-treatment, on which so much depends; and to Dr. Boyce for giving the anaesthetic in difficult circumstances.

This case is interesting because of the large size of the cerebellar abscess, the long duration of coma, the extreme emaciation and moribund condition of the patient, and his remarkably complete recovery. In such cases death is frequently the result of failure of breathing brought about by pressure on the respiratory centre in the medulla oblongata. Here the respirations had been reduced to four to the minute. The result recorded well exemplifies the favourable outcome which may be hoped for if such pressure be relieved in time.

in one corner of the abscess cavity. Pus was pursued in the proximal and distal portions of the sinus until a little clot was found, and free haemorrhage obtained at both ends. These were then plugged with small strips of ribbon gauze. The wound was left widely open, dressings applied, and the patient returned to bed.

Progress.—The patient appeared a little cyanosed, but made good progress until another rigor announced the formation of an abscess in the left subacromial bursa, which was opened. The lower end of the upper segment of the jugular vein also started to discharge through the opening which was left in the upper part of the incision in the neck. He again appeared to mend, until another sudden rise of temperature was caused by a patch of pneumonia in, and partial collapse of, his left lung. But in spite of that he continued to make good progress until the advent of the fog of December 10th, 1924, when he took a decided turn for the worse, possibly owing to the effect of the foul air upon his lungs. An abscess gradually developed in the lower lobe of the left lung, accompanied by a rise of temperature for fourteen days; but its contents were gradually coughed up, and the condition settled down. The temperature chart shows the various stages of the patient's illness. The post-aural wound cleared up well, and there was no further discharge. But a small plastic operation will be necessary at a later date to secure a good cosmetic result. A facial-hypoglossal anastomosis is also a matter for future consideration, but its desirability in this particular case is doubtful. The lung and shoulder lesions already referred to have both made favourable progress, and the patient is now well.

Points of Interest.

(a) **Factors against the Patient.**—(1) At the time of the operation the clot in the lateral sinus was about 2½ in. long, of which about 1½ in. had already suppurred. (2) Although the jugular vein was tied before any surgical interference with the sinus had taken place, metastases had already occurred.

(b) **Factors in Favour of the Patient.**—(1) When suppuration occurred in the lower end of the upper and isolated portion of the jugular vein, there was drainage awaiting it in the neck owing to part of that incision having been left open. (2) As soon as practicable the abscess in his subacromial bursa was opened and drained. (3) A metastasis occurred in only one lung and

respirations were not at any time very rapid. (4) The patient's own courage and apparent indifference to matters concerning his health.

My thanks are due to Mr. Herbert Tilley for the opportunity of operating upon and permission to publish this case; and to Dr. Batty Shaw and Mr. J. R. Hunter for kindly looking after the medical and general surgical aspects of the case.

In both of these cases the ear was not at first suspected on account of apparent cure of the aural condition. The result was that neither was operation on until the disease was so advanced that recovery seemed doubtful.

The conditions governing and the symptoms associated with cholesteatoma formation are such as to warrant some such general rule as follows: "That when anything goes seriously wrong with a patient who is suffering from, or has at any time suffered from, aural discharge, the ear should be suspected unless a diagnosis of some unconnected disease can be made with certainty, and the ear excluded." In such a case, unless the ear can be absolved, operation is indicated; because the risks run by an early operation are as nothing compared with the danger of delay. The safest course of all is to keep chronic suppurative middle-ear disease under observation, and perform a radical mastoid operation as soon as it is clear that no simpler measures will cure it, and before any intracranial complications have had time to develop.

CASE III.—*Staphylococcal Meningitis of Otic Origin: Operation: Recovery after Trans-theatal Irrigation.*

The patient, a small girl aged 2 years, was admitted to University College Hospital under Dr. Poynton on April 19th, 1925, suffering from signs of early meningitis, which was at once recognized as being of aural origin.

History.—On September 1st, 1924, the patient had been admitted to University College Hospital with an acute mastoid abscess of the right ear. This was successfully operated upon. Three weeks later the tonsils and adenoids were removed, and in another fortnight she was discharged apparently cured. On December 4th, 1924, she was again admitted with a profuse discharge from the nose and throat, as well as from the right ear. There was also an abscess beneath the scar of the previous operation. A conservative operation was again performed, in the hope of saving the hearing of the right ear. Unfortunately the next day the child was found to have measles and was removed to a fever hospital. When she returned to the ward the posterior operation wound was soundly healed, but the discharge from the external auditory meatus still continued and became foul-smelling in spite of thorough treatment by irrigation, which was carried out as an in-patient. The parents were therefore advised that it was necessary to convert the conservative into a radical operation in order to make the ear safe; but further operation was refused and the child was discharged from hospital. She attended later as an out-patient, but made no progress. Operation was again advised, and was refused, and the parents no longer brought her to the aural out-patient department. On April 2nd, 1925, she became giddy and frequently vomited her food; but the parents paid little attention until she became drowsy, when they brought her to hospital on April 19th.

On examination the child was drowsy, with intervals of unconsciousness. When aroused she screamed, and resented any movement or interference. Temperature 102.5°, pulse 120. The eyes were upturned under half-closed lids. No nystagmus in any direction could be elicited. Hot and cold water tests were not attempted owing to the condition of the patient. There was foul-smelling discharge from the right external auditory meatus. The left ear also was now discharging, and pressure over the left mastoid process was evidently very painful. The head was retracted, and any movement of it was resented. König's sign was indefinite. The knee-jerks were brisk.

A diagnosis of meningitis of aural origin was made and an immediate operation decided upon.

Operation.—(1) Under a general anaesthetic a lumbar puncture was performed and a test-tubeful of turbid cerebro-spinal fluid was evacuated under considerable pressure. (2) The left ear being the most acute, a radical mastoid operation was performed on this ear first. The middle ear and mastoid process were found to be full of pus, and a search was made for a channel of infection of the meninges, but none was found. The wound was then plugged with gauze, soaked in bipp, and dressings applied. (3) A radical mastoid operation was then performed on the right ear, and a large fistula was found in the lateral semicircular canal. The labyrinth was thereupon opened above the canal of the facial nerve. The promontory between the fenestra ovalis and the fenestra rotunda was then removed and the vestibular cavity found to contain serum. It was evident that the infection had passed through the labyrinth and lamina cribrosa (through which the eighth nerve enters the labyrinth) into the internal auditory meatus and so to the basal meninges. The lamina cribrosa was therefore removed so as to allow the basal cisterns as free drainage as possible along the route of infection. (This method of establishing intracranial drainage is known as the Scott-West method.¹) No cerebro-spinal fluid escaped when this was done, which is unusual. A short rubber drainage tube was

then inserted into the deep part of the cavity, and gauze strips soaked in flavine were packed around it. Dressings were applied, and the patient was returned to bed after being under an anaesthetic for an hour and a half.

Progress.—The following day Dr. Goodhart's report on the cerebro-spinal fluid was: "Pus cells in large numbers. No organisms seen. No growth after twelve hours." The patient was slightly less restless, but otherwise the condition was unchanged. Temperature 102.5°, pulse 120.

Irrigation of the Internal Ear through the Spinal Canal.—The same evening another anaesthetic was given, and turbid fluid sufficient to fill a test tube and a half was removed from the spinal theca. The needle was accordingly left in position, and the operating table tilted until the patient's head was considerably lower than the pelvis. The dressing was removed from the right ear, which was downmost, and some Locke's solution at body temperature was perfused through the spinal canal by way of the lumbar puncture needle, in the hope that some infectious fluid might be washed out through the internal auditory meatus of the affected ear.² This was successful in so far that some 3 c.cm. of fluid escaped from the deep part of the mastoid wound on that side, whereas none had previously drained away. The dressings of both ears were changed, and the patient returned to bed. At this time the pulse rate had risen to 160, there was some collapse, and the condition gave rise to anxiety. But during the night there was continuous improvement, the temperature fell to 99.5°, and in the morning the child was conscious and sensible; at lunch time she sat up and asked for pudding. The recovery was remarkably rapid.

Dr. Goodhart's report on the cerebro-spinal fluid evacuated the night before was as follows: "Pus cells ++; staphylococci in large numbers." But there was no growth in culture, and it was evident that drainage of the basal cisterns of the meninges and the internal meatus and ear was effected sufficiently early to prevent their reinfection through the ear, thus allowing the cerebro-spinal fluid to overcome the initial contamination.

The patient subsequently made good headway, and ten days later the incisions for each operation were closed by sutures after cutting the meatal flaps usually made in a radical mastoid operation. This could not be done at the time of the first operation owing to the necessity of establishing as free drainage as possible for both ears, and of getting the patient back to bed in the shortest possible time.

The child is now well.

I have to thank Mr. Herbert Tilley for the opportunity of performing the various operations on this case and for permission to publish it.

Sir William Milligan has differentiated three types of meningitis of otic origin: (1) Meningitis benigna (or serous); (2) meningitis maligna, in which pus cells are present in the cerebro-spinal fluid; and (3) meningitis maligna (in which both pus and organisms are present). Of cases in Type 3 only 2 to 3 per cent. have been known to recover, whatever treatment they received.³ From what I have seen of such cases the majority of the few cases of meningitis maligna which do recover appear to be staphylococcal.

THE NON-OPERATIVE TREATMENT OF PYLORIC STENOSIS.

BY

J. L. MEAGHER, M.B., B.S.M.E.D.

DURING a term in attendance at the Kaiser and Kaiserin Friedrich Kinderkrankenhaus, Berlin, in February and March, 1925, I was enabled, through the kindness of Professor H. Finkelstein, the director, to investigate the results of the non-operative treatment of pyloric stenosis. The following is an analysis of these results, and an attempt to estimate the value of the various kinds of feeding and medicinal measures.

The results of non-operative treatment are of interest because of the decided bias toward the operative procedure in England. German medicine has adopted a conservative attitude. Its resources are directed to postponing operation as long as possible. Statistics of successful treatment naturally are the criterion of the justice of this view. The results, so far as figures are available, appear to support it.

One of the points for decision concerning the treatment at the Kinderkrankenhaus was the efficiency of cereal feeding. The observations concerning cereal feeding are based on 14 cases. All were diagnosed as pyloric stenosis, and all were treated at the hospital in the period from November, 1920, to March, 1925, with feeding by cereals as a systematic part of the treatment. Various kinds of cereal mixtures were used of varying degrees of consistency. Whole-milk, half-milk, and buttermilk were used on occasion to form the basis. Maize flour was the chief stiffening agent employed. One of the mixtures was so thick that a spoon stood upright in it. In 7 cases the cereals were without beneficial effect; among them were 5 in which the effect was distinctly prejudicial. Particularly was this the case with the milkless cereals. In 5 cases cereal feeding was either a beneficial part of the treatment or was wholly responsible for the cure. In 2 cases the result was not discernible from the chart. My view of the evidence of the charts is that the disadvantages of feeding with cereals in the treatment outweigh the advantages. It is impossible from the point of view of a collator of results, in some cases years old, to say what were the factors responsible for the failure of the cereal feeding.

THE PERISTOLIC FUNCTION.

What is responsible for the failure of the cereal feeding? It should be noted that here there has been, not only a failure, but a failure attended with results threatening the lives of the patients.

The x-ray examination of the stomach of infants has served to reveal the existence of a peristolic function, exhibited by a marked change in shape of the organ and demonstrable through the use of thick cereals. Peristole in the stomach may be described as the capacity of the organ to accommodate itself to the mass of food ingested—a muscular action comparable with, and adjunct to, peristalsis. Rogatz of New York, working at the Kinderkrankenhaus, found that the stomach showed distinctly different contours with liquid and with semi-solid, or, more strikingly, with very thick feedings. With the fluid feeds the stomach shadow was of a pear or oval shape, horizontal in position, and extending to or beyond the mid-line, the air bubble being large or moderate in size; with foods of very thick consistency the stomach contracted to a circular or oval shape, barely reaching the mid-line, never extending beyond, and with a very small air bubble or none at all. The effect of thick cereals in producing this peristolic contraction was well shown by two babies suffering from pyloric stenosis, who for the occasion were fed with a milkless cereal. Observations I made in the Roentgenological Department in March confirmed in general the findings in respect of normal children.

Upon the basis of his observations Dr. Rogatz explained the vomiting in pyloric stenosis and of habitual vomiters by a mechanical action of the stomach musculature, and proposed a cure by mechanical means—thick cereal feedings. The action, in his opinion, is identical in both types. Peristole is the key to the control of the vomiting. It may best be evoked by cereals—the thicker the better. Vomiting occurs as a consequence of fluid feedings, which, so to speak, baffle peristolic action. With thick cereals less air is swallowed, the stomach content is correspondingly decreased and the organ has a greater area for surrounding and gripping the food.

If this view were correct it might have been supposed that successful results would have been gained in the treatment of pyloric stenosis by thick cereal feedings at the Kinderkrankenhaus. That they were not is explained by Finkelstein as due to a different mechanism of the vomiting in the two types of case. In pyloric stenosis, as in habitual vomiting, peristole is evoked by cereal feedings. The cause of the vomiting in the former class of case lies in the disordered function of the pylorus. On this ground the cure should be sought in treatment by antispasmodic drugs. The persistence of powerful peristalsis long after the vomiting has been controlled also suggests a constitutional cause for the vomiting which should be benefited by antispasmodic drugs. That the stomachs of these children are lacking in tone, at any rate in the later-developed stages of

the affection, is shown by the large residues which they contain, the lengthening emptying time, and the appearances on the x-ray screen.

THE TREATMENT.

A point of interest in connexion with the non-operative treatment is its justification by results. In a collection of statistics published in 1923, covering the experiences of German physicians since 1906, J. Ibrahim of Jena tabulates the mortality figures from eleven sources. These number 400 cases, and show a mortality of 10.2 per cent.—a more favourable percentage, he states, than that attending the then most recent surgery. The mortality in the 52 cases treated by him was 1 per cent. The mortality among the cases handled throughout by the non-operative treatment by Finkelstein in the last four years at the Kinderkrankenhaus amounts to 15 per cent. In this period 22 cases were treated; 16 recovered and 3 died. Among the deaths was that of a premature infant on the sixth day of treatment; another, admitted on the third day of life, died on the seventh; the third died of pneumonia after five weeks' treatment. The average duration of treatment to the time of cessation of symptoms was eleven weeks.

Feeding.

The aim of the feeding may be said to be to supply the baby with the maximum amount of nourishment he can assimilate. Concentrated feeding, therefore, holds pride of place, and it is immaterial which kind of concentrated food is used, so long as the caloric needs are met. The form of food used at the present time at the Kinderkrankenhaus is concentrated protein-milk (ciwies-milk) according to Finkelstein's prescription, without water, but with the addition of 20 per cent. of sugar (half cane sugar, half dextro-maltose). Breast-milk is used as well as the ciwies-milk, for its immunity value. Milk drawn from the mother's breast or, if this is not available, from a wet-nurse, is added to the ciwies-milk, and the mixture, heated to body temperature, is given to the baby in a flask. The feeds, small in amount, perhaps not more than 30 grams, are administered at intervals of two and a half hours. In the twenty-four hours eight feeds are given, or in the case of the youngest or weakest babies, ten feeds. Sometimes it is found of advantage to administer the food by means of a medicine glass or by a spoon instead of by flask. The baby is allowed to lie during the feeding, and afterwards is propped up at the side of the cot, supported by a pillow so that he may relieve his stomach of air by belching. Finally he is laid upon his right side.

During the entire period of the concentrated feeding, for months perhaps, the deficiency of fluid from which the baby suffers is made good by injections of Ringer's solution, administered rectally by means of a syringe, in amounts of 10 or 20 c.cm. five times in the day, or, if the need is urgent, peritonically or subcutaneously.

Manipulative.

The only practical manipulative procedure in the treatment is the washing out of the stomach. The indication is given by the size of the residues, as evidenced by the amount of the vomit and the measured quantity drawn off from the stomach. A weak solution of sodium bicarbonate, or a solution of "Karlsbad" salt, is used once, twice, or three times daily.

The Medicinal Treatment.

At the Kinderkrankenhaus, as elsewhere, atropine has proved of use. Even in large doses it is regarded as not attendant with danger to the child. It is given usually by the mouth as a 1 in 1,000 watery solution of atropine sulphate, half an hour before the feed. The precaution is taken to begin with a small dose, three or four drops, three times a day. The dose is increased if the indications warrant, until the child is receiving as much as 55 or 45 drops, given in doses of 7 or 9 drops five times daily. Ibrahim utters a warning against giving the drug in severe cases on an empty stomach. The drug is pushed until the symptoms of poisoning appear, if the severity of the vomiting warrants. Upon their appearance it is withdrawn, and

NON-OPERATIVE TREATMENT OF PYLORIC STENOSIS.

after an interval of one week or less, again given. This time the original dose is given and the amount is gradually increased. Reddening of the skin and dryness of the mucous membranes may be present without dilatation of the pupils. Sometimes the drug is administered subcutaneously. Ibrahim has given it for as long as nine weeks without observing ill effects.

It is difficult to assign to atropine with exactitude the part it plays in the success attending non-operative treatment. Of 25 cases in which the records were examined it seems to have produced good results definitely in 5 cases. The charts do not show that the efficacy of the drug was due to the larger doses, though this is the opinion of the director of the hospital. Where the larger dose has been used, naturally a happy result appears more striking. In the consideration of the efficacy of a particular line of drug treatment the task of freeing the operation of the drug from all the other factors present, of the working of the other drugs, of feeding, of infective complications, is a task of considerable difficulty. Clinically, therefore, the appropriate dose must be made the subject of trial. The charts are of cases treated with the drug in February and March, 1925. The action of atropine does not seem to consist in an immediate check to the vomiting; its good results are best perceived where it has been given for a period of weeks. The procedure followed at the hospital at the present time is to allow intervals in the administration of this and other drugs. In this way their influence is better seen.

Adrenaline has been used with success in the treatment, and it is claimed that it has been given at the Kinderkrankenhaus for the first time in association with atropine. In those cases in which the drug has been used in conjunction with atropine the practice has been to give them alternately in association with the feeding times.

Adrenaline is given intracutaneously in the forearm, ten minutes before the

feed, in the form of 1/4 mg. doses of suprarenin hydrochloride in a 1 in 1,000 solution. The child may receive this dose of adrenaline subcutaneously without effect. It has been given subcutaneously without effect. A definitely beneficial effect, due, as far as can be seen, to the drug itself, has been shown in the latest cases treated by it at the Kinderkrankenhaus. Where the feeding has remained unchanged in amount and nature the weight has increased and the symptoms modified distinctly toward the betterment of the patient; and charts show, what is surprising, that where there has been an intermission in the use of the drug the weight has fallen. It seems to have tipped the beam in the relative merits of atropine and adrenaline. Good results have been achieved in the use of both. The peculiarities of the individual may complicate the issue. Their action in combination in some cases seems fortunate. This partnership may be illustrated by the

analogy of a horse in harness. The removal of vagal influence may be likened to a slackening of one rein, and the stimulation of the sympathetic innervation to a corresponding tightening of the other. Other drug treatment at the Kinderkrankenhaus has not been successful. The following cases illustrate the medicinal treatment.

CASE I.

E. K., a girl, fed for four weeks at the breast, vomited explosively at the age of 5 weeks, and was admitted when aged 7 weeks, weighing 3,500 grams. Exaggerated peristalsis was visible and the pylorus was palpable. At the end of three weeks, having received atropine for nine days, the child was given adrenaline on two consecutive days, in the manner customary at the hospital. The weight curve showed an immediate rapid rise, and the vomiting, which previously had occurred from one to four times each day, became infrequent and ceased completely six weeks later. For whole-milk and cereal feeding, which had proved unsuccessful, breast-milk and concentrated eiweiss-milk was substituted, just before the adrenaline medication. The calorie intake was thus increased by 15 daily. The child was discharged after eleven weeks.

CHART 1.—Case I.

treatment, weighing 4,300 grams.

CASE II.

W. W., a boy, was described with justice by the sister in charge as possessing a tough constitution. He lost up to the time of his birth, which was at the age of 7 weeks, his weight betterment 35.6 per cent. of his body weight at birth, which was 4,350 grams. On admission, at the age of 7 weeks, his weight was 3,200 grams. He had been fed at the breast alone only for one week, and then received a supplementary milk mixture. He vomited with increasing frequency immediately after drinking, and on admission showed severe peristalsis and a palpable pylorus. He was weak and the water content of his tissues was lowered. He was approximately three months under treatment without benefit. The feeding at various times included concentrated eiweiss-milk, breast-milk, and whey. He was given a cereal feed composed of maizeena mixed with concentrated eiweiss-milk. The effect was greatly to increase the vomiting. He was given atropine until the appearance of a rash, and papaverine. Both were without effect. Washing out the stomach produced residues varying from 170 to 30 grams. After three months adrenaline was given on four successive occasions. The feeding at this time was concentrated eiweiss-milk and the vomiting decreased. The vomiting decreased. Afterwards his

CHART 2.—Case II. From the eleventh week of the child's age until and after the betterment of his symptoms in the nineteenth week, concentrated protein-milk combined with breast-milk was the chief feeding. Milkless cereal feeding, substituted about the twelfth week, caused a marked drop in the weight and was discontinued after less than two weeks.

breast-milk. His condition for the first time showed rapid progress continued. He suffered a short relapse due to pneumonia. Afterwards his

CONCLUSIONS.

1. A study of the cases leads to the conclusions: That thick cereal feedings usually do not benefit the condition.
2. That their failure is associated with the atonicity of the stomach musculature.
3. That concentrated feeding, coupled with the administration of atropine and adrenaline, is a serviceable non-operative treatment.

THE FUTURE OF GALL-STONES PATIENTS.

BY
GUSTAVE MONOD, M.D., M.R.C.P.,

AND
M. ROUZAUD, M.D.,
PHYSICIANS AT VICIGY.

THE localization of stones in the gall bladder and the surgical problem it often poses have dominated for a long time the whole history of biliary lithiasis. Until recent times the classical treatises dealt almost exclusively with the calculus, its migrations, its dangers, its local complications, and the ultimate effect on the liver. Murchison, however, was one of the first to note the frequent relationship, either immediate or remote, of gall stones with certain lesions, and with certain alterations in the tissues and viscera, in particular with gouty nephritis.

In explaining biliary lithiasis by a hypothesis of hypercholesterinaemia, Professor Chauffard enlarged the limits of the subject. From a purely hepatic disease biliary lithiasis has become a very much more general one. We can even detect its presence before the painful crises, and we can follow its insidious progress after they have disappeared. In the light of this new knowledge the role of the liver loses nothing of its importance. Without waiting for the formation or the migration of the calculi, we are in a position to appreciate the defect of the liver, whether it be congenital or acquired, which is at the bottom of the lithiatic tendency and which controls the local or general phenomena.

After having systematically followed, since 1912, the basic disorder underlying cases of biliary lithiasis, we have adopted in this research work the scheme of examination published by one of us, and which consists in (a) the study of viscosity of the blood by the method of Hess, and of the blood pressure by Pachon's oscillogometer; (b) the estimation in the blood of biliary pigments, of cholesterol, of urea, of residual nitrogen, of uric acid, and of glucose; (c) the estimation of the urco-secretory coefficient of Ambard.

During the course of this work we have relied solely on complete clinical and biochemical observations of patients in whom the diagnosis of gall stones was well proved, and have not availed ourselves of cases in which we had no opportunity of controlling our diagnosis by operation or x rays, or the actual passage of calculi.

Of the ninety cases under observation, six underwent complete examinations at long intervals—in one case the interval amounted to nine years, by which time the clinical picture was completely modified; the others were seen either at the actual onset of their trouble or else very much later. As a result of being able to follow up the same patient, or different patients, it appeared to us that it would be possible to trace the complete pathological progress of this disease—progress followed more or less rapidly by the majority of our patients.

Whilst the troubles are primarily of hepatic or humoral origin they become generalized slowly, insidiously throughout the whole body, presenting eventually a clinical picture which may seem to have little or no connexion with the liver. The rare exception to this rule occurs in cases in which the biliary colic was incidental, following a sudden simple rise in the blood content of cholesterol. Such a crisis constitutes the whole course of the disease. Predisposition is, we may say, necessary: "Ne fait pas de la lithiase qui veut."

For purposes of convenience we have divided these ninety cases into four groups to represent four main points of a curve. Actually each type of case may follow its course more or less rapidly. Some patients may remain perpetually in *statu quo*.

FIRST GROUP. (See Table I.)

The characteristics of the patients in this group, who are young (20 to 40) and present a clinical picture of acute or subacute biliary colic, are the following:

(a) The viscosity of the blood is normal or slightly increased.

(b) The arterial pressure is normal.

(c) Cholaemia is constant, but rather low, if we except

those cases which are accompanied by a retention of bile due to calculi.

(d) Cholesterinaemia is increased, but rarely rises above 2.10, except in cases of complete biliary obstruction. In certain cases, however, it is not rare to find cholesterinaemia which is normal, or only slightly raised, after a crisis terminating in the expulsion of biliary slime or calculi, as if such a crisis represented an effort towards the elimination of cholesterol from the system. In a previous work we have cited six cases of this nature, which we may compare with cases of renal calculus in which hyperuricaemia is controlled by an abundant elimination of uric acid.

(e) Protein metabolism is fairly normal, if we may judge by the output of urea and residual nitrogen. Uric acid, however, is almost invariably increased, and this early association between the increased amount of cholesterol and uric acid in the blood is, in our opinion, evidence of some hepatic derangement leading to lithiasis. This hyperuricaemia gives rise to no clinical symptoms, since the kidney function can be shown to be intact by estimating Ambard's coefficient of excretion-secretion.

(f) Lastly, it is very frequent to find in these cases a slight increase in the blood sugar. Without doubt, in such an increase may be found the explanation of the fact that certain of these patients pass sugar or are liable to become diabetics.

To summarize, in this first stage towards lithiasis: so long as the clinical symptoms are purely liver symptoms, our biochemical examinations seem to prove that the trouble is rather biliary than hepatic, since the liver cell retains its activity and the cardiac and renal apparatus are unaffected. From this point patients may take either of two routes: some, the exception, remain subacute or chronic stone cases, the gall-bladder symptoms remaining pre-eminent and sometimes exclusive; these will be found in the second group. The others (the majority) cease to be purely hepatic cases; they tend towards complications of a more general character and will be found in the third group.

SECOND GROUP. (See Table II.)

In these cases the viscosity of the blood is raised and the arterial pressure is found to be variable. It is not uncommon to find dilatation of the right heart. Cholaemia is raised without a parallel increase in cholesterinaemia. Such a dissociation shows the cells of the liver to be affected—a fact which is further evidenced by the marked increase of the residual nitrogen, of the uric acid in the blood, and of the ammonia content of the urine. The blood sugar remains slightly raised. The urco-secretory coefficient goes somewhat up without an increase of the blood urea, and the urea concentration of the urine shows no deficiency of the kidneys.

Clinically we easily recognize this type of patient with active congestion of the liver and the resulting symptoms of portal engorgement. This defensive active congestion, by means of which hypercholesterinaemia is controlled, eventually hampers the general circulation, and, the right heart giving way, a secondary and passive congestion ensues. Under the influence of these repeated stages of congestion the liver cells gradually lose their activity, and biliary cirrhosis, especially of the left lobe, becomes the predominating feature. In these cases the renal and cardiac troubles maintain an obvious connexion with those of the liver. But more often these patients, as time goes on, suffer less: they have, perhaps, eliminated several calculi; they do not complain of their liver, and their general state improves.

THIRD GROUP. (See Table III.)

In these cases the following characteristics may be noted. Viscosity is increased, and this concentration of the blood can be explained by increased diuresis, which is the means adopted by the already damaged kidney to prevent an accumulation of toxic products. The uric acid concentration of the urine is gradually lowered from 15 to 12 or even 10 grams per litre, and the coefficient of Ambard may rise above 0.1, indicating a reduction of from a third to a half of the renal function. The arterial pressure is markedly raised, especially in the diastolic phase, but generally, owing to the raised systolic and hypertrophy of the heart, the circulatory compensation is adequately maintained. These are exactly the characteristics which Martinet described as pre-sclerotic.

* Second examination.

Cholaemia is slightly, and cholesterinaemia is markedly, raised. This is the period at which chronic gall-bladder cases present local deposits of cholesterol. Chauffard has well shown that the system endeavours by all possible means to eliminate from the blood stream any excess of cholesterol.

Residual nitrogen and uric acid, less markedly increased than in the second group, are nevertheless above normal; the cells of the liver are less affected than in the latter group, but the deficiency of heart and kidney is more marked. It is the factor which will assume the supreme importance in the fourth group.

FOURTH GROUP. (See Table IV.)

In this group heart failure sets in and the blood gets more and more diluted. Albuminuria appears at the same time. The urea concentration of the urine falls coincidentally and Ambard's coefficient, by its increase of value, shows a progressive degeneration of the kidney. Hypercholesterinaemia remains very high, as also does the nitrogen and uric acid content of the blood. In brief, the cases in this group present the humoral characteristics of Bright's disease. As a matter of fact, these results enable us to trace the connexion between lithiasis and the condition underlying Bright's disease, and tend to verify the hypothesis of Chabanier that such a nephritis is the final development of a general condition.

CONCLUSIONS.

From the preceding facts we can draw the following therapeutical conclusions.

The gall-bladder localization must not be considered as the only guide to correct treatment. It can only be used to determine the need for surgical intervention. The essential treatment must be based on the conception of a general metabolic disorder, previous to calculus formation, in which the liver plays the predominant part. The safety-valve furnished by the biliary apparatus is of the utmost importance; it can act by preventing general and local complications.

Whilst therapeutic measures are practically ineffective once complications of the cardiac and renal systems are established (when symptomatic treatment is the best that is available), it is possible in the periods preceding painful or insidious lithiasis to amend and correct the function of the liver by more effective therapeutic measures than have previously been employed.

TREATMENT OF SLEEPING SICKNESS.

BY

A. T. SCHOFIELD, M.R.C.S., L.R.C.P.,
C.M.S. HOSPITAL, TORO, UGANDA.

Previous to July, 1924, the routine treatment of sleeping sickness in the C.M.S. Hospital, Toro, had been by atoxyl injections, with varying success. In July 50 grams of "Bayer 205" were sent by the principal medical officer and six cases were selected for comparative observation. Two were of the severe cerebral type, showing the later stages of the disease; two were of early cerebral type, with considerable glandular involvement; two were fairly early cases, with slight involvement of glands, etc. All came from Katwe or the Semiliki river area. In only one instance (severe cerebral type) had the patient received any previous injections of atoxyl three and four with only slight improvement. The blood contained trypanosomes in each patient except one early case, in whom the gland juices were positive.

One gram of "Bayer 205" was, as advised by Kleine, given to adults intravenously, in 10 c.cm. physiological saline, on the first, third, fifth, twelfth, and seventeenth days. Routine examinations of the urine were made, but no albuminuria or other toxic signs, found by others, were observed, and no ocular symptoms.

The blood examinations after the first injections were negative in every case. I fully appreciated the need of observation of the cerebro-spinal fluid, and only abandoned

the attempt after very careful inquiry and consideration. The compound is a voluntary one, attached to a missionary hospital, and it was thought that such a painful operation would be extremely likely to drive the patients away and keep others from coming, thus negating the work of years.

The treatment was given in July and August, 1924, and in October and November all but the two severe cases were discharged at their own urgent request. Blood and gland examination in every case were then negative, and the patients had been completely free from every sign or symptom of the disease for three months (the single possible exception is detailed below).

I persuaded the two "cerebral" cases to remain for longer observation, by promising gifts, etc. One had, in September, a slight return of drowsiness in the day time, but trypanosomes were not found (he refused spinal puncture); I accordingly gave them both three further doses at weekly intervals. The history of these two cases is worth recording.

CASE I.

Juma, a man aged 28, when admitted on June 16th, was sleeping nearly all day; he was emaciated (weight 5 st. 13 lb.), incontinent, and there was coarse tremor of the tongue, etc.; glands much enlarged. Examination of the urine was negative. Trypanosomes were present in the blood. Temperature 92.2°, pulse 123.

An intravenous injection of atoxyl was given on June 17th and repeated on June 24th. On June 30th his weight had increased to 6 st. 1 lb., and he was not sleeping so much. On July 15th he was given 1 gram of "Bayer 205" intravenously. The following day the temperature was 99.6°; no trypanosomes were found in the blood, and there was no albuminuria. He had not slept all day. The "Bayer 205" was repeated on July 17th, 19th, and 20th, and on August 12th. On August 11th his weight was 6 st. 11 lb., and he was not sleeping in the daytime; there was some tremor; he was able to answer questions. By September 4th the patient's weight had increased to 7 st. 4 lb.; he was reported to have been drowsy in the daytime during the last two days. He was given 1 gram of "205" on this day, and again on September 11th and 18th. On October 7th his weight was 7 st. 6 lb., and he was free from symptoms; there was, however, some tremor, and the glands were still much enlarged.

CASE II.

Everina, a girl aged 16, when admitted to hospital on July 2nd was sleeping nearly all day; she had been incontinent, and answered questions only after repeating three or four times. There was coarse tremor, and glands were very much enlarged; no ocular symptoms were present. Weight 4 st. 9 lb.; temperature 92.4°, pulse 116. Trypanosomes were found in the blood.

On July 15th 0.7 gram of "Bayer 205" was given intravenously; there was no reaction; no albuminuria, etc. Temperature 99.6°. The following day there was no reaction; the patient did not sleep during the day; no trypanosomes in the blood. On July 25th her weight was 4 st. 12 lb.; she was smiling and answered questions; tremor less; no trypanosomes. On August 11th she was quite bright; weight 5 st. 4 lb. On September 4th she was given 0.7 gram of "Bayer 205", and again on September 11th and 18th. By October 7th her weight had increased to 5 st. 6 lb.; there were no symptoms, though there was still some tremor.

The later history of these two cases is very unfortunate, but interesting. It points to the necessity for prolonged observation and, if possible, examination of the cerebro-spinal fluid.

On October 16th I went on Safari. Both patients were then apparently quite well and still gaining in weight. No symptoms had been observed. They had both wanted to return to their homes and it had taken considerable persuasion to induce them to remain. While I was away on Safari, on October 19th, both patients, apparently without any premonitory symptoms, went into the comatose final stage of the disease. They became incontinent and died within twenty-four hours. Such a rapid course is unusual in my own experience, and I think might be considered by a biologist for his explanation. The native attendants are quite emphatic in saying that there was no return of symptoms up to within a few hours of the comatose stage, while I myself saw them four days before. It was unfortunate that I was away when this occurred. The blood had not been examined for two months.

The other four cases are reported to be still well after eight months (March, 1925).

Summary.

1. "Bayer 205" is immensely superior to any drug previously tried.

2. It caused trypanosomes to disappear from the blood in twenty-four hours in the severest cases.

ACUTE RETROBULBAR NEURITIS.

JAN. 16, 1926]

3. It cannot yet be considered to be a cure for late cases, though definitely ameliorating the patient's condition and restoring normal life for some months.

4. Late cases should be kept under compulsory control—for example, in some prison lines—with examination of the cerebro-spinal fluid.

In conclusion, I must add that I have also made a trial of tryparsamide, a supply of which drug was furnished in October, through the principal medical officer, by the Rockefeller Foundation. A similar series of six cases was selected, but was unfortunately broken up, after three injections, by five of the cases running away after a spinal puncture for cerebro-spinal fluid examination of one case. This misfortune points to the need of careful, plodding preparation before making any further attempt at spinal puncture, or else putting some cases aside for the purpose, but not in the same area. Each case, however, had improved remarkably and seemed completely free from the disease.

Three cases have now been under observation for over three months, apparently completely cured. No reaction or toxic effects were noticed after the tryparsamide injections.

The results are difficult to compare with the "205" results. However, the clinical impression left on my mind is that tryparsamide is equal, if not superior, and is easier to work. I intend to use the tryparsamide as a routine, as long as the supply lasts.

I am indebted to the Principal Medical Officer, Uganda, for permission to publish these notes.

TEN CASES OF ACUTE RETROBULBAR NEURITIS.

BY

FRANK HECKFORD, M.R.C.S., L.R.C.P.,

LATE OPHTHALMIC HOUSE-SURGEON, ST. BARTHOLOMEW'S HOSPITAL.

DURING the last six months an unusually large number of cases of acute retrobulbar neuritis were admitted to the ophthalmic ward of St. Bartholomew's Hospital. These cases are of interest inasmuch as in no one of them was any satisfactory cause of the condition found, and in all but two there was rapid recovery of vision.

There are a certain number of cases in which the cause is clear, such as disseminated sclerosis, diabetes, and various toxic conditions; but reference to writers on the subject shows the frequent occurrence of cases in which the cause is unknown. A very large list of diseases held responsible has been compiled; this includes rheumatism, gout, dysentery, intestinal stasis, tubercle, syphilis, sinusitis, septic tonsils, typhoid, and many others. Sphenoidal sinusitis has been blamed for a great many cases, and the sinus drained, with subsequent rapid improvement of vision. This, however, is the normal course of events in a majority of cases, and therefore not necessarily a result of the operation. Mr. Foster Moore states that he has never seen a case of retrobulbar neuritis that he was satisfied was due to paranasal sinusitis. All these cases, accompanied by skiagrams and x-ray reports, were examined, with negative results, by Mr. Rose in the throat and nose department of the hospital.

The outstanding features of the condition are rapid loss of central vision with neuralgic pain in the eyeball, made worse by movement of the globe or pressure of it back into the orbit; impairment of the activity of the pupil to light; absence of gross disc changes; and a tendency to rapid recovery. The following is a short summary of each case.

Case 1.—A woman, aged 27. Noticed pain in the right eye, followed a week later by defective vision in the same eye. Vision: right, 6/60; left, 6/9. The right pupil reaction was sluggish. The peripheral fields were complete, but there was a small central scotoma in the right field. The fundi were otherwise normal in appearance. The Wassermann reaction was negative. There was no evidence of any sinusitis. Dr. Hinds Howell reported the absence of signs of organic disease of the nervous system apart from the optic nerve. After eight weeks the vision was 6/9.

Case 2.—A woman, aged 20. Pain in the right eye, followed a week later by defective vision. For one year she has had a twitching of the left side of the face and neck. Vision: right, 6/12; left, 6/9. She complained of tenderness of the right eye. The reaction of the right pupil was sluggish. The peripheral fields were complete, but there was a relative scotoma in the lower temporal region of the right field. The fundi were of natural appearance. It was reported that there was no manifest sinusitis. Dr. Hinds Howell found no evidence of intra-ocular sclerosis.

Case 3.—A woman, aged 26. Left eye became misty two weeks before admission. Three weeks previously she had had pleurisy. Vision: right, 6/6; left, counts fingers at one metre. The left pupil was inactive to light. The visual fields were complete. The edges of the left disc were blurred, but the fundi were otherwise of natural appearance. No evidence of manifest sinusitis was found. There was no organic disease of the nervous system.

Case 4.—A woman, aged 32. Frontal headache and pain in the six days after admission the vision was 6/6. Vision: right, 6/6; left, 6/12. Both pupils were active to light. There was a general contraction of the peripheral field, and a small central scotoma. There was optic neuritis, but no haemorrhages and no exudates. The left fundus was of natural appearance. Mr. Rose reported that clinical examination did not arouse suspicion of sinusitis. There was no evidence of organic disease of the nervous system. Seven weeks later the vision was 6/9.

Case 5.—A woman, aged 20. Sudden fogging of vision and pain on touching the eyes. Vision: right, 6/24; left, 6/36. The right pupil was active, but the action of the left pupil was sluggish. The visual fields were complete. Both optic discs were swollen, the left more than the right. The Wassermann reaction was negative. Nothing abnormal was discovered in the central nervous system, and there was no sinusitis. Eighteen days later the vision was much improved: right, 6/12; left, 6/6.

Case 6.—A woman, aged 40. Right eye became misty three weeks before admission to hospital. No pain was noticed at any time. Vision: right, large moving objects; left, 6/6. The right pupil did not react directly to light, but reacted consensually. There was loss of the nasal half of the right field and of the inferior temporal segment of the left field. The fundi were of natural appearance. The Wassermann reaction was described as border-line. Mr. Rose reported that there was a small polyp in the left nostril, and he believed there was ethmoiditis on the right side, but he could find no evidence of it on the right side. There was no evidence of organic nervous disease. The vision was not improved one month later.

Case 7.—A woman, aged 22. Impaired vision of the right eye, and pain in the same eye on looking to the left. Vision: right, less than 6/60; left, 6/12. Both pupils were active. The peripheral fields were full, but there was a central scotoma in the right field. In the right fundus great tortuosity of the vessels and distension of the veins was to be seen. The disc was surrounded by small haemorrhages. The left fundus showed the same condition of the arteries and the veins, but no haemorrhages were seen. No sinusitis or organic nervous disease was to be seen. Three weeks later the vision was 6/24.

Case 8.—A woman, aged 24. Pain in the right eye, which became worse on looking to the left. Vision: right, less than 6/60; left, 6/6. Both pupils were active. There was a central scotoma in the right field, but no contraction of the peripheral fields. The right optic disc was swollen, and there were haemorrhages in the fundus. The left fundus was of natural appearance. The Wassermann reaction was negative. Mr. Rose reported that there was no sinusitis. Dr. Hinds Howell found no evidence of intra-ocular sclerosis, nor of any lesion in the nervous system beyond the papilloedema. Four weeks later there was no improvement.

Case 9.—A man, aged 39. Pain on looking to the left, followed two weeks later by failure of vision, especially of the left eye. Vision: right, 6/36; left, perception of light. Both pupils were active. There was some contraction of the nasal part of the right visual field. The right fundus was of natural appearance. There was some swelling of the left optic disc, but no haemorrhages. The Wassermann reaction was negative. There were two septic teeth in the lower jaw. Mr. Rose reported no manifest sinusitis. There was no disease of the nervous system. Three weeks later the vision was: right, 6/9; left, 6/24.

Case 10.—A man, aged 45. Pain on movement and failure of vision in the left eye. Vision: right, 6/6; left, less than 6/60. Both pupils were active. There was a general contraction of the left visual field. The left disc was slightly swollen, and one haemorrhage was to be seen. The Wassermann reaction was negative. There was no sinusitis and no evidence of organic disease of the nervous system. Four weeks later the vision was 6/36.

Diagnosis.

Although in one or two of the cases the diagnosis was reached by a process of exclusion, it may in general be accepted as correct. In all but two of the cases there was pain as well as defective vision. In four this pain was made worse on movement of or pressure on the globe. A scotoma was found in five of the cases, and in four there was some peripheral contraction of the field of vision. In five cases there were marked pathological changes in the disc. In five of the cases the activity of the pupil was

impaired, and in the remaining five the contraction was not maintained.

Cause.

Although all the reputed causes mentioned at the beginning cannot be excluded with certainty, there is no positive reason for thinking that any one of them was responsible. The most important cause to be considered is disseminated sclerosis, and in these cases careful examination failed to reveal any sign of the disease at the present time. Cases have, however, been reported where retrobulbar neuritis has been the first and only sign of the disease, and other manifestations have only come to light so long as ten years or more afterwards.

Neither tubercle nor syphilis requires serious consideration, and in this series in all but one case, which was described as doubtful, the Wassermann reaction was negative.

The controversial question in a group of cases of this sort is that of paranasal sinusitis. As already stated, many cases have been operated on by rhinologists and the sphenoidal sinus drained, with subsequent rapid improvement of sight, but that this is in most cases the normal course of events is not realized. Consequently, an improvement which may be none other than the ordinary course of progress of the disease has been attributed to the operation. As already stated, thorough examination of the air sinuses was carried out in all these cases, and no evidence of any infection was revealed.

This series of cases seems to demonstrate the existence of a group of cases of acute retrobulbar neuritis, which have no demonstrable cause, and which are certainly not due to sinusitis. There is no doubt that a considerable proportion of them will ultimately reveal themselves as cases of disseminated sclerosis.

I am indebted to Mr. Foster Moore for his assistance with these notes, and for permission to publish the cases.

DIATHERMY IN THE TREATMENT OF PROSTATIC OBSTRUCTION.

BY

T. E. HAMMOND, F.R.C.S.,

ASSISTANT, SURGICAL UNIT, WELSH NATIONAL SCHOOL OF MEDICINE;
CONSULTING UROLOGIST, WELSH NATIONAL MEMORIAL ASSOCIATION
AND THE ROYAL HAMADRYAD HOSPITAL, CARDIFF.

THE idea of burrowing a channel through the prostate in cases of obstruction to the outflow of urine is probably as old as the hills. In more modern times it was recommended by John Hunter. In 1834 Guthrie invented a catheter containing a concealed blade for dividing the bar at the neck of the bladder; and in 1876 Bottini of Pavia introduced his galvano-cautery incisor with the aim of preventing haemorrhage. In spite, however, of opportunities that were only too numerous, the one method which was regarded as of any value at the end of the last century was the passage of a full size metal bougie, which was retained in the urethra for a few minutes. When the more modern methods of perurethral treatment are considered it should be remembered that a certain amount of relief was thus obtained. When more precise instruments became available "forage of the prostate" was recommended by Luys and the "punch operation" by Young. The operator, however, worked in the dark and under great difficulties; severe haemorrhage was common, and the obstructing mass was either crushed or burnt away with the cautery. The immediate results in cases that came under my observation were poor. Though I have not been able to follow up any series of cases, it would seem that scars resulting from such wounds must follow the course shown in other parts of the body and later contract and give rise to a stricture at the neck of the bladder. These methods received little support in other countries, and never came into favour in this.

In 1910 Beer first applied diathermy to growths of the bladder, which were destroyed by electro-coagulation. This

was the first practical method of treating such growths through the urethra, and had the advantage of being carried on in a water medium. Though sloughs were produced that took two weeks to separate, no infection followed and haemorrhage was never severe. The scar, unlike that resulting from open operations upon the bladder, did not contract and pucker up. This feature of the diathermy scar is well seen in the face, where, after the removal of rodent ulcers, the scar remains soft and supple, and differs very markedly from those which follow burns and scalds. At that time the difficulty in

applying diathermy to prostatic lesions was that, while the obstructing mass could be clearly seen, the electrode could not be applied to it through the ordinary cystoscope. About 1916 cysto-urethroscopes of the Brown-Bunger type were introduced, with which the surgeon worked from the prostatic urethra; with these not only could the parts adjacent to the neck of the bladder be seen, but the electrode could be applied to the obstructing mass under the control of the eye. Since 1913 I have by means of this instrument treated cases of prostatic obstruction by diathermy with much success; but it takes two or three weeks for the slough to separate, and during that time micturition may become more difficult and the passage of a catheter may be necessary. The diathermy punch of Mr. Kenneth Walker is a great improvement, as now we have an instrument by which the obstructing mass can be seen, destroyed by diathermy, and removed at the same time. In the series of cases I have been able to follow up no stricture has formed.

When the operation of prostatectomy became popular in the beginning of this century, it was limited to the senile or so-called adenomatous enlargement. A perfect functional result followed, provided no malignant changes were present, and a mucous membrane flap was prevented from forming over the prostatic cavity. As the technique of the operation improved and the mortality diminished, it was found that in some cases the functional result was not so good. If from these cases were eliminated those where the symptoms were due, not to lesions of the prostate, but to diseases such as tabes, and those where malignant changes were present, the remainder fell into three main classes: (1) Those in which the prostate was atrophied or there was slight thickening round the bladder neck, the so-called "prostatitis sans prostate" of Guyon, or the prostatic bar to which Guthrie first drew attention in 1830. (2) Those in which the prostate was small and fibrous. (3) Those in which the prostate was large and fibrous. These cases were characterized by the difficulty in removing the prostate, which was torn out rather than enucleated, by the shock and the amount of bleeding that followed, and by the prolonged convalescence, during which it was often necessary to pass sounds to keep the orifice dilated. Urinary symptoms persisted after the operation, and many of the cases died after a year or two with wasting and cachexia. Some surgeons regarded this as due to malignant changes, though none was found in the part of the gland removed, nor could any signs be detected on rectal examination. Death really resulted from renal failure and an infection ascending to the kidneys, both secondary to a stricture at the neck of the bladder.

When studying the pathology of the prostate it should be borne in mind that it is a secondary sexual gland, which, like the breast, undergoes involution about the age of 45. The adenomatous enlargement has been compared to the cyst-adenoma of the breast, and, like it, can be easily shelled out from the surrounding tissues. The different conditions found in the prostate are sometimes regarded as modifications of this; that, I think, is a mistake, for if they are not distinct pathological entities, they are at any rate very definite types of the same disease. Just as in the breast there may be a hypertrophic or an atrophic mastitis, so in the prostate there may be a large or a small fibrous prostate, and even atrophy of the gland itself, quite apart from the local changes in the glands of Albarran that are situated round the bladder neck. While the adenomatous enlargement tends to become progressively larger, this is not the case with the other varieties, for they are fibrous in type, and after reaching a certain size

remain stationary, or even tend to become smaller. Whether the fibrosis is the result of an inflammatory or a degenerative change I am not prepared to say; possibly both types occur. When an attempt is made to enucleate such prostates there is a tearing through of the fibrous tissue, which later contracts to form a stricture. And it is this tearing through of a gland that is richly supplied with nerve fibres, instead of enucleating in a plane of cleavage, that is largely responsible for the operative shock.

When the adenomatous enlargement affects the lateral lobes the urethra is compressed throughout its length. Removal of the obstructing mass by diathermy is very difficult, and, as the enlargement is progressive, the relief obtained is at the most temporary. On the other hand, when the middle-lobe alone is enlarged, the obstruction is limited to the bladder neck, and if not of a very large size can be removed by the diathermy punch. But both these types of enlargement are those most suitable for enucleation, and should not be submitted to diathermy, except, perhaps, where the middle lobe is slightly enlarged and the symptoms are not sufficiently severe to justify a major operation.

With the fibrous and atrophied prostates the urethra is not compressed throughout its length, and the obstruction is at the bladder neck. When the bladder is opened in these cases it will be found that there is a narrowing of the internal meatus, but that when the finger is passed through this the prostatic urethra appears more dilated than usual. Here we have a type of prostate that does not tend to become progressively larger and where the obstruction is localized to the bladder neck; the latter can be easily destroyed and removed, and does not tend to recur. After treatment by diathermy shock and haemorrhage are never severe enough to cause any worry, the convalescence is much shorter than after prostatectomy, the functional result is better, and the mortality is less. In 20 cases done so far by me there has been one death. When it is remembered that the type of prostate which is treated by diathermy is that which is largely responsible for the mortality after prostatectomy, it is obvious that a careful selection of cases will lead to an improvement in the statistics of this operation.

Should infection of the bladder or signs of renal failure be present and no improvement follow catheterization, a preliminary cystostomy is advisable. It may appear reasonable that, as there is now an opening in the bladder, the best line of treatment at the second stage would be removal of the gland. A preliminary cystostomy, however, does not make the operation of prostatectomy easier; it makes it, if anything, more difficult, and merely improves the condition of the patient so as to diminish the operative risk. Consequently the indications for treatment by diathermy will be all the more urgent here.

There is, of course, a danger of malignant disease arising in the part of the gland left behind; this has happened in one of my cases. Surgeons with a large experience of prostatectomies will, however, have come across cases where, after the removal of an apparently simple adenomatous prostate, malignant changes have developed in the part of the gland left behind. The temporary relief I had hoped for from diathermy in malignant prostates did not ensue; and here the operation is not worth while. This is probably due to the obstruction being throughout the prostatic urethra and not localized to the neck of the bladder.

So far as the clinical selection of cases suitable for diathermy is concerned, little difficulty will be experienced in the small fibrous and the atrophied prostates. When a rectal examination is performed in the latter the finger comes up against the posterior wall of the pubis, the hardness of which may lead to the impression that one is dealing with a malignant prostate. The examination carried out with a metal bougie in the urethra enables this error to be avoided. With the large fibrous prostate a careful cystoscopic and rectal examination is essential, and sometimes the differentiation between this and the adenomatous enlargement is by no means easy. The fibrous prostate is somewhat firmer, and on rectal examination there is not that projection backwards into the rectum, nor on cystoscopic examination that projection into the bladder, which

is found with the adenomatous prostate. The following cases are typical of my series.

1. W. C., aged 50, was sent to me by Dr. Bowen-Jones with a history of difficult micturition for five years. In August, 1922, the symptoms became worse, and were not relieved by the passage of metal sounds. In December, 1922, attacks of retention occurred, and in January, 1923, he was admitted under the surgical unit. Rectal examination showed atrophy of the prostate, and cystoscopy a bar over the internal meatus. The bar was destroyed by diathermy applied through the cysto-urethroscope, and he was discharged from hospital with a good stream and no difficulty. In August, 1923, obstruction to micturition again developed. Cystoscopy showed a tag of mucous membrane attached to the posterior lip of the internal meatus, which was destroyed by diathermy. Since that time he has been able to micturate without difficulty and has now no urinary symptoms.

2. W. R., aged 66, was sent to me by Dr. Jeffrey Jones with a history of frequent micturition since 1918 and difficulty for three months. In November, 1921, there was a diffuse enlargement of the prostate to be felt on rectal examination, and the bladder was midway between the pubis and umbilicus. In December, 1924, he was admitted under the surgical unit. There were marked signs of renal failure, and the blood urea was 80 mg. No improvement followed the tying in of a catheter, and a preliminary cystostomy was done on December 18th; during the next two days the tongue became dry and the blood urea rose to 120 mg. The general condition then improved, and as cystoscopy showed no large intravesical projection, diathermy was applied to the region of the internal meatus on January 7th, 1925, and again on January 26th. Following each of these applications there was no shock and no signs of uraemia, the blood urea not rising above 60 mg. The suprapubic tube was later removed and the fistula closed. When seen one month ago he had a good stream, there was no undue frequency of micturition, and no residual urine.

Summary.

1. The application of diathermy is useful in certain cases of prostatic obstruction.
2. It should not be employed in the adenomatous prostate where such good results follow enucleation.
3. It should be reserved for the large and small fibrous prostates and the atrophied prostate.
4. Its application in these cases leads to a better functional result and a lower mortality than after prostatectomy.

In conclusion, I wish to express my indebtedness to Professor A. W. Sheen, director of the surgical unit, for the facilities he has placed at my disposal and for many useful suggestions.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

ERYSIPELAS TREATED BY FOREIGN BLOOD INJECTION.

THE note by Dr. Pines (December 5th, 1925, p. 1062) on the value of haemotherapy in erysipelas leads me to record the following case treated last May.

A Moroccan Jewess, aged 49, on whom I performed a submucous resection of the septum, was discharged from hospital after the usual forty-eight hours' stay. When she returned for inspection on the fifth day after operation a patch of erysipelas the size of half a crown involved the left ala nasi and extended towards the left lower eyelid. She had not used the nasal wash provided. In spite of nasal washes, followed by careful drying and dusting of the site and the usual methods adopted in such cases, the erysipelas spread rapidly, the left eye becoming involved.

On the seventh day, with the patient lying on her right side, 20 c.c.m. of blood was removed by a cold non-cituated syringe from a vein in her right arm, and without delay injected intramuscularly into the left buttock, which had been previously prepared. The whole procedure was a matter of seconds, and so much was her attention concentrated on the withdrawal that she was quite unconscious of the buttock injection, for before leaving she asked how long the blood analysis would take, and would not believe that the blood had been injected. The effect was dramatic, for in the course of the next two or three days the erysipelas rapidly faded away.

When a wound is complicated by erysipelas the subsidence of the latter is usually followed by rapid healing or cleaning of the former, and so it was in this case, for with the clearing of the eruption the infection of the nasal mucosa rapidly diminished.

In making blood injections the longer the blood remains in the syringe the greater the colloidal change occurring in the protein particles of the plasma; such change is beneficial, and so some slight delay should be made in transferring the blood. In this case, owing to climatic conditions in Tangier, delay was inadvisable.

London, S.W.

J. NISSEN DEACON.

LABOUR COMPLICATED BY UTERO-VESICAL FISTULA.

The unusual conditions present in the following case are the reason for placing it on record.

A woman, pregnant for the second time, was brought to me from a distance of about a hundred miles for confinement. She had been married four years, and had a child after a difficult labour two years ago. Convalescence was fairly normal, but she had continuous dribbling of urine. She was sent to me as a case of difficult labour, the local midwives having failed to do anything for her. She was seven months pregnant, and labour pains had started three days before her admission; the membranes had ruptured about the same time. On admission the pulse was 120 and very feeble, and the temperature was 102°. A foul red discharge was present and her general condition was bad. Abdominal examination showed no signs of any focus, but by rectal examination a foetal head was felt lying on the perineum.

The vagina was very shallow, admitting a finger to the depth of 1½ inches only; no signs of cervix or fornices were present. One inch from the urethral orifice there was a small opening admitting a finger with difficulty; the edges of the opening were rounded and hard, almost cartilaginous in consistency. A red discharge was seen coming out of the opening. On passing a soft rubber catheter through it a small quantity of urine and blood was withdrawn. There was obviously a large utero-vesical fistula, both the uterus and bladder communicating with the vagina through a small opening. As no abdominal operation was possible I incised the posterior edge of the opening, and, on exposure, another hard band was felt higher up, obstructing delivery of the head. This also was divided and the decomposed foetus was removed. The patient died thirty-six hours later of septicaemia.

Apparently there had been much sloughing after the first delivery. She menstruated through the fistula, and had also conceived through the same opening. The second band I divided was probably the os, but as no necropsy was possible I cannot be quite certain.

ADELINE RUBINS, M.B.,
D.T.M. and H.Lond.

Lady Lansdowne Hospital, Bhopal.

APPENDICITIS IN A HERNIAL SAC.

The chief interest in the case here recorded is the youth of the patient.

A Malay boy, aged 5, was transferred from an out-station hospital, whither he had been taken for treatment for subtertian malaria, to the Malay Hospital in Kuala Lumpur on September 18th, 1925, because a right inguinal hernia, present since birth, had been irreducible for twenty-four hours; there was no great disturbance of pulse or temperature; vomiting had occurred, but was not severe or persistent. The hernia was serotol, and presented a tense, rounded, non-resonant swelling without impulse.

Before I saw him he had been given an enema, and an ice-bag had been applied. The enema produced an action of the bowels, in which were thirty-five round-worms, but the hernia remained unaltered. As operation is not, as a rule, one of the treatments in favour with Malays, I was relieved to get the father's consent to it.

On exposing the sac and opening it the appendix was found. Both were intensely congested, and the sac tore easily. On making traction on the distal end of the appendix it was found to be held in the fundus of the sac by a mass of oedematous fat, which readily broke away from the appendix, and was extracted separately. It was at first thought that the appendix was strangulated by the neck of the sac; on passing the finger up, however, no constriction was found, but a necrotic patch on the appendiceal wall. The caecum was lightly adherent above the internal ring, and enough of it was easily drawn down to permit of the usual removal and invagination of the stump. There was no sign of constriction of either the appendix or its mesentery. The sac was separated from the cord and ligatured as high as possible. The tunica vaginalis was reconstituted by a purse-string suture. A small drain was left in the inguinal canal for twenty-four hours and only the external oblique muscle and the skin were sutured.

The wound healed by first intention, and no trouble ensued for lack of drainage of the iliac fossa; a collection of pus in the tunica vaginalis had, however, to be evacuated by incision six days later. Recovery was otherwise uninterrupted.

I think it is safe to assume that the appendix had occupied the sac for some considerable time, and that the symptoms were due, not to strangulation, but to appendicitis.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

SOUTH-WESTERN BRANCH.

At the annual meeting for 1925 of the South-Western Branch of the British Medical Association, held last summer, Mr. L. C. PANTING, F.R.C.S., honorary surgeon to the Royal Cornwall Infirmary, Truro, delivered his presidential address. His subject was the present position with regard to malignant disease, and the lines along which advance in its treatment may be hoped for. The following is an abridged version of Mr. Panting's address.

Malignant Disease: The Present Position.

There seems to be no doubt that the incidence of cancer has considerably increased in recent years. Deaths from this cause have about doubled in number between 1830 and 1920; during this period the average age of man has considerably advanced, but the incidence of cancer does not seem to have altered proportionately, and cancer cases occur at least as early in life as they did forty years ago. I will therefore discuss the efforts being made to find its cause and the way Nature attempts to deal with it; along these lines only can we look for cure.

Turning to the experimental method, which is the only scientific method, we find two general lines: (1) investigation of the normal and of the malignant cell, together with their mutual relation; (2) investigation of the relation of the malignant growth to its host. These lines converge and sometimes cross as the work proceeds, but I think that the division is broadly true.

There is at the outset, unfortunately, great difficulty in deciding what may be considered as a true malignant growth. There is a gradation between what is called a pre-cancerous condition and true cancer; and there is also the question of the relation of experimentally produced conditions to cancer. In recent years a technique has been developed by which individual cells can be cultivated and transplanted in much the same way as bacteria are dealt with. It is found that a simple saline medium, such as tyrode, is sufficient for cellular life, but for growth and multiplication the addition of some organic material is necessary. Tissue cells are divided into two classes—those which require embryonic tissue extract, and those which can digest and utilize serum. Of the first class fibroblasts and pavement epithelium have been obtained in pure culture and maintained in healthy condition for a year or more. The addition of serum inhibits their growth, and this inhibition becomes more marked as the age of the donor increases. Of the second class—those cells which digest serum—large mononuclear leucocytes, thyroid cells, and other types have been obtained in pure culture. In both classes the cells remain true to type, and do not revert to their embryonic forms. The growth of the cells appears to depend entirely on the medium; waste products must be removed and certain necessary ingredients be present. Fibroblasts and epithelial cells require stimulants for their growth (hormones) and food for their sustenance (trephones); these are absent from adult serum, but present in embryonic tissue. We must hence conclude that embryonic cells can produce these substances from the protein of the egg or the blood of the mother, while the cells of the adult have no longer this power. It is further believed that the blood contains stimulating and inhibitory substances acting in opposition and that in post-natal life the inhibitory substances are in excess. Considering the medium and not the cell as the controlling factor, it follows that fibroblasts do not find the substances required for their growth in the blood, since otherwise they would overgrow rapidly and block up all the vessels. Mononuclear leucocytes and cells of the second class can, however, multiply on serum, digest it, and, since leucocyte extract contains hormones and trephones, it is probable that they can convert the serum into these substances and so enable the fibroblast and epithelial cells to grow in certain circumstances, as in the case of tissue reaction in a wound.

The next step was to investigate similarly the malignant cell: for this purpose a Rous sarcoma was chosen, since from the ground-up growth a filterable virus could be obtained which, when inoculated, reproduced the original growth. The sarcoma consists chiefly of fusiform cells, but when cultivated in a suitable medium several forms of cell appeared—polymorphonuclears, large mononuclears, and lymphocytes, as well as fibroblasts. From this growth pure cultures were obtained of large mononuclears and fibroblasts, the other types of cell disappearing. Each of these cultures, after sufficient time had elapsed for the disappearance of the virus from the medium (it soon disappears in the presence of serum), were injected into fowls. From the fibroblasts no result was obtained, but with

the large mononuclears the birds developed malignant growth with metastases and died. The next step was to attempt to convert a normal mononuclear into a malignant cell by inoculation with the virus, and to compare the cell thus infected with the normal. Normal mononuclear cells were obtained in pure culture from blood, and this culture was infected with filtered Rous virus. All the cells were found to be malignant in inoculation, and though some few behaved like normal cells the majority underwent a specific change after three or four days. The cells became granular and vacuolated, multiplication decreased, then agglutination occurred and brought about digestion of the medium. Later the mononuclears disappeared progressively from the coagulum, and from the mass of amorphous tissue there migrated triangular and spindle cells with their cytoplasm full of granules, some resembling normal fibroblasts; digestion proceeded rapidly, and finally all the cells died out. The filtered supernatant fluid was virulent. The conclusion drawn from this observation is that normal mononuclears can absorb the Rous virus and protect it from the destructive action of the blood serum; that in absorbing the virus the cell becomes diseased and short-lived; that the dead cells then infect other cells, and so the process goes on; that the tissue of the dead cells forms nutriment for the fibroblasts and other cells of the host, which increase and form the bulk of the tumour as seen in the affected animal. While the tumour cell is not anarchic or endowed with unusual vitality, but is short-lived and diseased, the tumour can grow rapidly and persistently.

This work of Carrel seems to open up a new field of research which may lead to far-reaching results. We want to know what happens when an epithelial cell is infected, and what is the virus to which it will react. The virus of Rous sarcoma has been studied by Gye, who obtained it by grinding up the original sarcoma, filtering the fluid, first through sand and paper pulp, and finally through porcelain. The filtrate, which reproduces the original sarcoma when inoculated, contains a particulate organism, which can be cultured; it differs, according to Gye, from the ordinary micro-organisms only in its minute size. Similar filterable organisms have been described as the cause of small-pox, chicken-pox, and encephalitis lethargica. Hort, however, has put forward the view that the micro-organisms which we are accustomed to look upon as fixed types are in reality only one phase in the life-history of the organism, and that the other is the minute form just mentioned. Further work is clearly needed before this question can be settled.

On the second line of research—namely, the relation of the malignant growth to its host—the chief work has been the study of the conditions associated with the development of cancer in man and in animals. It has long been known that workers in tar, crude paraffin, arsenic, and some other chemicals are liable to cancer of the parts exposed to their action to an abnormal extent. Mice, painted on the back with tar thrice a week, lose the hair on that part, and almost invariably develop warty growths in from three to six months. Of these growths one only becomes malignant, with atypical cells and metastatic growths, the others gradually disappearing. If this malignant growth is removed surgically no further malignant development can be obtained by repeated paintings with tar. If the painting is stopped shortly before the time at which warts usually develop, the condition progresses just as if the painting had been continued. Thus the cancer has, so to speak, a long incubation period, and some sort of immunity is developed. Cancer is often found in association with other diseases: the ova of bilharzia may be associated with cancer of the bladder in man, and the ova of *Taenia crassicolis*, given to rats in food, produce liver cysts which may be accompanied by sarcoma. Febiger found that in rats with the rare condition of carcinoma of the stomach a minute nematode worm was present in the carcinoma. When he learned that nematodes had been found in rats fed on cockroaches, he fed some normal rats on this diet, but without results until he tried a particular kind of cockroach, *Periplaneta americana*, with which he obtained cancer of the stomach in 50 per cent. of the rats and found the nematode in the cancer. To determine whether purely mechanical irritation is the cause of cancer as opposed to chemical irritation, Leitch implanted gall stones and ordinary pebbles into the gall bladders of guinea-pigs, and obtained growths in 25 per cent. of the animals. These growths invaded the liver directly, but there were no metastases, and the cells lining the tubules of the growth formed only a single layer. There is, therefore, some doubt as to the malignancy of the growth, but the conclusion drawn is that irritation alone is a sufficient cause of cancer.

One general conclusion from this work is that cancer, however local it may appear, inhibits the development of another cancer in the same subject—that is, it produces a certain immunity. That immunity can be developed in animals by breeding has been proved by Maud Slye, who succeeded in breeding a strain of mice immune to sarcoma, and another strain so sensitive to it that every inoculated mouse died. Another

conclusion is that specific forms of irritation assist in the production of cancer, and that the cancer arises at the site of the irritation. The irritation theory is largely held by clinicians and pathologists, especially in America, where surgeons have stated that some 50 to 60 per cent. of cancers of the stomach arise from old gastric ulcers. Moynihan believes that some 20 per cent. of gastric ulcers become malignant, and Sherren gave this figure as 25 per cent. Dible, however, after a special inquiry, stated that out of 126 cases where the clinical and naked-eye appearances indicated gastric ulcer, no single case showed malignant change on microscopic examination, and that out of 164 stomachs removed for ulceration, simple or malignant, only 5 cases were found in which, on histological evidence alone, the appearance might be taken to mean that malignant disease had been grafted upon a chronic ulcer. Finsterer, on the other hand, out of 145 apparently simple ulcers found 31 cancers. There is similar doubt as to the pre-existence of chronic inflammatory disease in cancer of the breast; general opinion favours this view, but Raymond Johnston is strongly opposed to it.

There appears to be a reaction against the general doctrine of irritation as a cause of cancer, and there are certainly conditions of chronic irritation, such as ulcers of the leg, which rarely lead to cancer. The alternative view, moreover, must be considered, that cancer is the cause and not the result of some at least of the chronic inflammatory changes seen. It is now generally believed that in chronic cancer some at least of the cancer cells are destroyed by the body tissues, and it may be asked whether it is not possible that the earliest formations of cancer also are sometimes destroyed and never mature, but leave behind them a condition of chronic inflammation. Cancer is believed to spread by the lymphatics and the blood stream as well as by direct infiltration; and along each of these lines we find evidence that the body tissues resist its invasion. In the primary growth this is shown by the small cell infiltration always present at the growing edge, and by the masses of fibrous tissue surrounding the islands of malignant cells. The same process is shown where the cancer is growing as a solid cylinder along the lymphatics, or, to use Handley's term, "permeating" them.

In our complete ignorance of the relation of sarcoma to carcinoma, it has been assumed that they are of the same class and probably arise from a similar cause. Sarcoma is a disease of youth and is rare; carcinoma is a disease of advancing years and is becoming more frequent; is it not possible that this may be explained by the gradual development of racial immunity against sarcoma, which affects man before the age of reproduction, while this has not been developed against carcinoma, since it hardly affects the multiplication of the race?

We are no longer in the hopeless position when cancer was looked upon as a disease apart from all others in which some of the body cells had for no reason become anarchic and turned traitor to the body, and for which no other treatment could be conceived than that of total extirpation. This method holds the field to-day, but we can reasonably expect better things to come. We have seen that a disease resembling closely, though probably not identical with, cancer can be produced by a virus; that individual types of cell can be cultivated *in vitro*; that some of these can be infected with a filterable virus and its effect observed on the infected cell, as well as on the animal as a whole. May we not hope to learn soon which of the cells, in cancer as we know it, are the real agents; and what is the cause, living or otherwise, which leads to their activity? This would be a long step towards rational treatment. On the side of the host we have found evidence that the tissues are not entirely overwhelmed, but do react against the invasion by cancer, though their efforts nearly always fail. This should surely guide treatment. Even now it would seem that we have learned something of the lines on which to work, for by means of radiant energy rodent ulcer or basal-celled carcinoma can be cured. This is not a mere caustic action such as could be obtained by a red-hot iron, but an action which enables the cells of the body to deal with the lesion themselves. Knox is advising repeated small doses of α rays to stimulate the reparative powers of the cells in their fight against malignant disease rather than the single massive dose of the Erlangen school, aimed at destruction of all the cancer cells—and others. Scott takes a similar view, and says that for the cure of carcinoma with α rays certain unknown biological factors play an important part: radiations do not destroy or remove unwanted cells like the cautery or knife, but profound changes are set up by which malignant cells are replaced by normal tissues without necrosis occurring—a metamorphosis without cellular death. In practice he irradiates the whole body. Lazarus-Barlow suggests that irradiation produces antigens, which in turn produce antibodies, for if certain tumours are given a heavy dose of irradiation outside the body, and a portion is then injected into an animal, that animal becomes immune to inoculation with the tumour.

Various metallic salts, including copper, selenium, and potassium, and the injection of toxins (Coley's fluid) have been

tried without much success, but the use of a lead compound is on a different plane. Blair Bell has stated that the chorionic foetal cells invade the pregnant uterus in the same way that cancer cells invade surrounding tissues, but that after a certain period this invasion ceases in normal cases. Under abnormal conditions invasion continues, and chorion-epithelioma follows. Since this disease does not appear before the foetus has either died or been expelled, it is argued that some foetal substance may inhibit this persistence of growth, to the withdrawal of which malignant development is due. Blair Bell considers chorionic cells as malignant cells under control, and cancer cells as normal cells freed from control. This cell tension theory of cancer appears to have been contradicted by Carrel's work. Blair Bell, having failed to obtain from the foetus the inhibitory substance, has employed lead, which has long been known as an abortifacient, and has shown that it has a specific poisoning effect on embryonic cells, as well as on nerve cells, blood cells, spermatozoa, and malignant cells. All these cells contain phosphatides, and the action of lead is thought to be concerned with this chemical group. To lessen the danger of lead poisoning a colloidal preparation is employed, and there appears to be a specific clinical effect, shown by the appearance of pain localized in the growth in two to eight hours after injection, as well as some local reaction. The amount of lead found in the growth is far larger than that in any other portion of the body except the gonads. Some cases which had failed to react to x rays improved with lead, and, conversely, some previously treated with lead improved when x-ray treatment was instituted.

For the present, however, total extirpation by surgery must hold the first place in the treatment of cancer, though, apart from some improvement in technique and greater knowledge of the lymphatic spread, but little advance can be expected.

Reports of Societies.

LIFE ASSURANCE MEDICINE: ITS PROGRESS AND LIMITATIONS.

At a meeting of the Assurance Medical Society on January 6th Dr. OTTO MAY delivered an address from the chair, taking for his subject the progress of life assurance medicine and the obstacles still in the way of an ideal assessment.

Dr. May began by remarking on the increasing responsibilities of the medical examiner. Originally the medical examiner had only to advise acceptance or rejection of a proposal; now, in the case of an impaired life, he was required to investigate the nature and extent of the impairment and its effect on the prospects of longevity. With this increasing range of duties had gone a rapid advance during the last thirty years in clinical, and particularly in laboratory, methods for the investigation of bodily function. Some of this advance was more apparent than real. It was not to be assumed that all change was progress, and that each new discovery was a milestone on the road to omniscience. When he looked through the early *Transactions* of the society, which was founded in 1894, and saw the wealth of clinical knowledge and judgement displayed in the papers, he had an uneasy feeling that the more recent elaboration of methods had not proved an unequivocal blessing. True, if one were able to command for life assurance work all the resources of the modern hospital or clinic, it might be possible to arrive at a better estimate of the proposer's condition than was customary thirty years ago. But life assurance was essentially a business proposition, not an exercise in the niceties of laboratory methods. The examination was limited by the extent to which the proposer would submit to the trouble and expenditure of time involved and by the amount of cash outlay which the assurance company was prepared to sanction. When, as often happened, the proposer was indifferent to the outcome, it was obviously difficult to get him to submit to, for example, a test of his sugar tolerance curve. It was obvious also that a company would hesitate to sanction any large outlay except in the case of proposals for large amounts; in the case of doubtful proposals for smaller sums the company would prefer either to decline them outright or to come to a decision on such information as was contained in the ordinary report. It followed, therefore, that in the large majority of proposals

even now a decision had to be reached on the findings of the ordinary clinical examination, and it was at least arguable that, owing to dependence on laboratory methods, which in these cases were not available, the modern practitioner was less, rather than more, skilled than his predecessor of thirty years ago.

Examination for Arterial Pressure and for Heart Function.

One point in routine examination in which there had been real advance was the measurement of arterial pressure. In Dr. May's view the introduction of the sphygmometer into clinical medicine had been one of the few real diagnostic and prognostic advances of recent years. He hoped that the time would soon come when the measurements of both systolic and diastolic pressure by the auditory method would become an essential part of every life assurance examination. This would enable, in the course of a few years, a large quantity of statistical material to be amassed, which would furnish results of considerable interest as to the relation of diastolic pressure to mortality. He summarized certain statistics which he contributed to the discussion on hyperpiesia in the Section of Medicine at the last Annual Meeting of the British Medical Association.¹

Another respect in which there had been some progress in routine examination during the last three decades was the increasing recognition of the importance of tests for myocardial efficiency. The estimation of the field of cardiac response by an exercise tolerance test in which attention was paid, not only to the variations of pulse rate, but to the amount of distress and the nature of the sensory symptoms evoked, was a definite advance. As far as he was aware, he was a pioneer when, in 1913, he introduced an exercise tolerance test as one of the items in the examination forms used by his company. In passing, he gave it as his opinion in all seriousness that it was a bad day for life assurance when the stethoscope was first applied to the heart; this had done more to confuse the issues between proposer and company than many people realized. An enormous number of perfectly good lives had been rejected, and, what was worse, made unhappy and invalided, by the discovery of a perfectly harmless "murmur," and a number of thoroughly bad lives had been accepted as a result of the examiner's reliance on the stethoscope as the practical arbiter of the heart's condition. He felt that, in spite of the undoubted advances due to the "new school" of cardiology, the stethoscope still loomed too large in the perspective of the heart examiner. A third respect in which advance had been made was in the recognition of different types of pulse irregularity, especially the ability to differentiate that due to premature contractions (extra-systole) from that due to a fibrillating auricle.

Albuminuria and Glycosuria.

Dr. May turned next to certain special methods of investigation placed at the disposal of life assurance examiners for the estimation of functional efficiency, such as tests of renal function, sugar tolerance tests by estimation of blood sugar, skiagraphy, especially of the chest and abdomen, the Wassermann test, and the electro-cardiograph. What he had said with regard to the application of the stethoscope applied also to some extent, though less strongly, to the introduction of urinary tests into the routine examination of the individual. Was there any medical examiner who was not tired of the recurring problem presented by the apparently healthy proposer in whom was found a trace of albuminuria or glycosuria? For medical prognosis the most useful methods of estimating the functional capacity of the kidney as an excretory organ appeared to be the estimation of the blood urea (and non-protein nitrogen) and the urea concentration test associated in this country with the name of Maclean. With regard to the former, he thought it might be accepted that a urea content greater than 40 mg. per 100 c.cm. was evidence of renal impairment; the converse, unfortunately, was not true, and the urea figure might be little, if it

¹ Mortality in Relation to Hyperpiesia, BRITISH MEDICAL JOURNAL, December 19th, 1925, p. 1166

all, increased in cases of serious kidney disease. The test, therefore, was useful in confirming the presence of serious kidney trouble, but not in excluding it. With regard to the urea concentration test, its place in life assurance medicine might be summarized as follows: a proposer whose urine failed to attain a urea concentration of 2 per cent. after the oral administration of 15 grams must be regarded as suffering from definite impairment of renal function; if the examination of the urine and the general condition of the proposer suggested the presence of "granular kidney" the attainment of this concentration must be regarded as a favourable sign that the kidney involvement was slight. If the urine examination, on the other hand, suggested the presence of parenchymatous nephritis, the test had no value in assisting to a favourable prognosis, as many cases had been recorded in which the urea concentration was normal in the presence of advanced parenchymatous nephritis. As to the other tests of renal function, he doubted whether any of them would find a practical application in this branch of medicine, and altogether, except for a limited help from the urea concentration test, there did not seem to have been any appreciable progress in the last twenty years in attempts to assess the risk in cases of albuminuria.

The position with regard to the assessment of glycosuria was very different. Thanks to improvements in the technique of blood sugar estimation, the curve of the blood sugar percentages following the administration of 50 grams of dextrose was now comparatively easily obtained, and was a most valuable help in determining the significance of glycosuria. This represented a very real advance in method, and enabled guess-work to be replaced by accurate knowledge. He had availed himself of this test in a good many cases of glycosuria; some of them had been shown to be of undoubted renal origin—an abnormally low threshold—and these had been accepted at ordinary rates if all other conditions were favourable. Others had been proved to be diabetes of slight or grave degree; in a few the result was of doubtful significance.

Altogether, he thought it might fairly be said that there had been some definite advances in the thirty years under review, and that there were reasonable hopes of still further advances in the future. But when all was said and done, there was something in the examination of a proposer which was beyond the range of clinical instruments or laboratory analyses. He meant, the general impression conveyed to an experienced examiner. An examination might fail to reveal any definite defect, and yet the examiner felt instinctively that the proposer's prospects of longevity were below par, that what, for want of a better term, might be called his vitality was poor. This was one of the most important factors in assessment, and the more the methods of examination were elaborated the greater was the risk of overlooking this aspect.

Assessment of Impaired Lives.

In the assessment of the extra risk for impaired lives there was less evidence of progress during the period under review. For all practical purposes the methods remained entirely empirical, and the examiner was left to translate some physical defect into terms of time or money with little to guide him except tradition and instinct. The assessment in most cases implied a compromise between hopes and fears, a desire to protect the company from undue risk, and yet not to kill the company's business. Very rarely indeed was it based on any actual knowledge of the effects of the particular impairment on the expectation of life. Not many life assurance examiners, he feared, possessed the true statistical mind; still fewer realized exactly what was involved in the ordinary method of assessment. It would be an excellent discipline for them to try their hands at superposing on a normal mortality curve their idea of the curve for some particular case which they were attempting to assess. To what extent did a moderate degree of myocardial damage affect the expectation of life? It would be entertaining, if not flattering to the pride, to compare the answers of all the members of that society in an examination paper set on such lines. Yet this was the problem that implicitly they set them-

selves to solve whenever they ventured to rate up a proposal. Was it not rather futile to go to considerable trouble to determine the exact degree of impairment of the proposer when the translation of this into assessment rested on so vague and unsubstantial a basis?

The fault, if there was any fault, did not rest entirely or chiefly with the doctor. Strictly speaking, the doctor should never be called upon to make an assessment; that should be the duty of his colleague the actuary. In actual practice, perhaps, it might best be done, as it frequently was, by the two in consultation. There was need for a joint medico-actuarial investigation on a wide scale, aiming at the production of mortality experiences for all the ordinary impairments, from data large enough to eliminate the fallacies arising from insufficient cases. Dr. Otto May's conception of the ideal basis for assessment was for medical men, in committee, to draw up a list of all the important defects likely to be encountered in their work, for the actuaries then gradually to accumulate the experience of the offices, and in course of time evolve from this material the mortality for these different classes. It might be advisable to subdivide some of the classes into slight, moderate, and severe. In the case, then, of a proposer suffering from one or more of these defects the essential duty of the medical officer would be that of stating to which class or classes the proposer belonged, and the actual assessment would be made by the actuary from these data. In this way the assessment might ultimately become more rational and consistent than at present, though, in view of the enormous amount of data required and labour involved, he was afraid it might be many years before this was ultimately achieved.

DISCUSSION.

Dr. H. M. ANEL agreed as to the value of the special and up-to-date methods of investigation, but feared that time and expense would continue to bar the way. Only the previous week his office had to postpone practically *sine die* a proposal because an electro-cardiographic examination was not possible. More might be done, however, in the way of enlisting the co-operation of the private medical attendant of the proposer. He had been glad to hear Dr. May's references to blood pressure, and he thought everyone would agree that some of the opinions expressed about five years ago needed revision. The estimation of the diastolic pressure was of the utmost importance, and without both diastolic and systolic the picture was inadequate. It must be admitted that difficulties and fallacies surrounded the estimation of diastolic pressure. At some future time it might be possible in this and other matters to establish a standard method.

Dr. G. G. HOWITT said that it was sometimes useful to impress upon proposers that for their own sake, in order to know where they stood, it was desirable that more elaborate tests should be undertaken. Some of them would, when this point was put to them, promptly undergo such tests for their own satisfaction. With regard to blood pressures, he was afraid these were often taken by men who had not read up or thought out the uses of the instrument they were employing.

Dr. H. W. COLLIER said that if the chief medical officer of a company was confronted only with the record of a high systolic pressure in a comparatively young proposer, he was in a position of considerable difficulty. In many cases if further investigation were made it would be found that the diastolic was perfectly normal, and that the increase in the systolic was simply due to an overacting heart at the time. The speaker thought that the society might well take the initiative in a very important advance in assurance science by encouraging the collaboration of the medical officer and the statistician, by pressing for uniformity in methods of accumulating and presenting statistics, by gathering together the experience of British life offices in connexion with substandard lives, and by arriving at some general agreement on the assessment of extra risks.

Dr. R. A. YOUNG said that assurance work, naturally, having regard to its particular conditions, had to be eclectic and utilitarian. The special methods of investigation mentioned by Dr. May had established themselves as extremely useful, but the difficulty was the expense and time involved,

TREATMENT OF PHTHISIS WITH SANOCRYSLN.

which sometimes made them prohibitive to the proposer. With regard to the diastolic pressure, he hoped no office would insist on this finding until that society or some similar body had established it, and also a table or list universal method of recording it, and also a table or list giving its indications. He knew what he himself meant by diastolic pressure, but he did not know what anybody else meant, and he was not at all clear yet as to the significance of a high diastolic pressure; he was inclined to a thing to be looked at askance. Nor did he know the effect of emotion on diastolic pressure; he was inclined to think that the diastolic was a more permanent and less alterable factor than the systolic, but of this again he was not sure. He hoped at all events that the diastolic would not be put on the forms of any office until definite instructions were given as to what should be the criterion. Dr. May had touched upon the different points of view of the medical officer and the actuary. The speaker had always maintained that the medical officer was concerned with the individual, and the actuary, of course, with the collective results. It was all very well to bid medical examiners to take a wide view and to consider things from the collective standpoint, but it was forgotten that their work was judged by their assessment of the individual case. He approved Dr. May's suggestion that the actual assessment should be done by the actuary on the basis of the report by the doctor. He also agreed with what Dr. May had said with regard to the undefinable something about certain proposers which led one instinctively to think of them as bad lives. What the examiner hoped when confronted with this class of person was that he would find some defect sufficiently definite to justify him in advising his company to decline or postpone the proposal.

Mr. KELHAM (assistant actuary, Prudential Assurance Company) agreed that it was inevitable that medical men should look on their cases as individuals, while actuaries were in search of a type to which every case could be referred. But when Dr. May spoke of the need for collecting and tabulating statistics somewhat along the lines of the American investigation of 1912, it must be borne in mind that the actuary was in the same difficulty as the chief medical examiner who received various reports without knowing exactly how they had been arrived at. It was very difficult to get together a homogeneous set of facts; one could never be quite sure how they had been compiled, and what material had come together in the various offices making up the whole experience. It was difficult also to get a wide enough experience which was sufficiently modern, for, of course, it was of no use going back over a long period, because much of the experience gathered in the early part of it would not be relevant to the experience gathered in the later. But because there were difficulties in the way, that was no reason for turning the suggestion down.

Dr. STANLEY BORSFIELD said that it was often found that the one doubtful factor in assessing a report was the systolic pressure. Before any proposer was rated up or declined on the ground of the systolic pressure, a second examination, and possibly (if there were wide differences between the first and second) a third, should be made, and he had always found the examining doctor ready to fall in with a polite request to verify his first figure.

Dr. P. R. INGRAM said that his office had given up the idea of putting on so many years for a life; it had gone back entirely to the old mortality basis. It was much better to think in terms of mortality, and leave the actuaries to deal with it, than with a number of years—for example, 150 per cent. would represent so many years' load at a certain age, 175 per cent. so many more. From the medical aspect he thought it much better for the companies in this country to deal with the matter on a mortality basis altogether. With regard to blood pressures, his office had insisted on both the systolic and the diastolic, but those conducting the examination had had to be educated in a definite way of taking these pressures. In his opinion the right time to take the diastolic was at the sudden drop in sound, but obviously that would lead to so many errors in examination that the method had been adopted of recording when all sound disappeared. The diastolic reading, he thought, was the most important part of the whole record.

Any reading over 100 meant a very suspicious case, and if the systolic dropped with a rise in the diastolic this was even more suspicious.

Dr. ORRO MAY, in replying, said that it seemed to him that to think in terms of mortality was likely to be quite as illusory as to rate up so many years. The medical assessor had to draw upon his imagination in the one case as in the other. With regard to blood pressures, there seemed to be a difference of opinion as to whether the diastolic should be asked for at present. It was well not to be in too much of a hurry; there were enough fallacious figures as it was, and this figure was likely to be more fallacious than the rest. It was desirable to await the spread among practitioners of further knowledge as to the value of these methods. In regard to a joint medical-actuarial investigation with a view to improving the method of assessment, he thought it might be useful to suggest such a course to the Life Offices Association.

TREATMENT OF PULMONARY TUBERCULOSIS WITH SANOCRYSLN.

A COMBINED meeting of the Sections of Therapeutics and Pharmacology and Medicine of the Royal Society of Medicine was held on January 12th. with Dr. GRONER, Chairman, the president of the Section of Therapeutics, in the chair, when a discussion on the treatment of pulmonary tuberculosis with sanocrysin was opened by Professor T. R. ELLIOTT, F.R.S.

Professor Elliott referred briefly to the passage of sanocrysin through the body; after intravenous injection it was rapidly excreted by the kidneys and to a less degree by the intestine. After four or five days its concentration in the blood and lungs fell rapidly, and the salt tended to accumulate elsewhere, particularly in the kidneys. The symptoms following its injection were as a rule very slight, unless there was a vascularized area of infection in the body, when a severe reaction might follow. If the drug was unduly pushed, hyperpyrexia and shock might ensue, with evidence of poisoning of the skin, liver, and kidneys. These conditions had been attributed by Danish observers to tubercle toxins, and they were a real danger. Professor Elliott had treated eleven cases, including three of tubercle infection and one in which no definite diagnosis of tuberculosis was made. Of the seven other cases, two patients had died, but this was not attributable to the salt, since both patients had very advanced disease before the treatment started, and there was no evidence that the sanocrysin had in any way hastened the end. In one case there was for some time considerable doubt as to whether the treatment was of any value. The physique of the patient was very poor and no benefit had followed any other treatment. After receiving the high doses which were customary at that time, anorexia, vomiting, and albuminuria followed, and the patient lost ground generally. During subsequent residence at home, however, under not very good conditions, she made good progress, and at the present time it appeared that complete arrest of the disease had been obtained, nor was there any sign of kidney trouble. Sanocrysin appeared to produce an increased local vascularization around the sites of infection, but there was no evidence yet that it killed tubercle bacilli. No benefit had followed its use in a case of tuberculous glands. In another case, a lad aged 18, with early but rapidly spreading pulmonary disease, great improvement followed the administration of an initial dose of half a gram, followed a few days later by a second dose of a gram. There was a reaction with the appearance of a rash, but no albuminuria. The temperature fell to normal, and the three following doses, each of a gram, produced only slight reactions. The sputum became free from tubercle bacilli, and the patient remained well during the course of sanatorium treatment which followed. Professor Elliott believed that the best results were seen in cases which reacted with some pyrexia and a rash, albuminuria seemed to be related to the amount of the salt given and the interval between the doses. In another case of pleurisy and peritonitis in which other treatment had failed over a period of three months, sanocrysin cleared the fluid out of the abdomen in three weeks. A boy aged

14. with infected glands in the neck and chest, developed pulmonary disease after surgical treatment, and became critically ill. He reacted sharply to sanocrysin, and the temperature dropped to normal, while the weight improved markedly, though there was but little change in the consolidation of the lung. At present, though he had returned to work, he was not well, and the improvement appeared to have been only temporary. Professor Elliott believed that sanocrysin produced quicker improvement in pulmonary tuberculosis than did any other treatment.

Professor JYLE CUMMINS had treated twenty-five cases and reported the results obtained in six patients who had been dealt with not less than six months previously. Very decided improvement had occurred in four cases, but relapse had followed. In the first case there had been definite improvement in disease at the left apex, as shown by radiological examination; weight was lost during the treatment but was regained later. The patient was then transferred to a sanatorium, but left it six weeks later, contrary to advice, and returned to rather unsatisfactory home conditions. Although there had been no haemoptysis or sputum yet the cough and general weakness had returned, and a second course of sanocrysin was now being given. The second case, a lad with apical disease, improved very much under sanocrysin treatment. He returned to work in a mine without having any sanatorium treatment and gained weight while at work. The sputum, however, reappeared, and was found to contain tubercle bacilli, so a second course of sanocrysin was commenced. The sputum then ceased and a course of sanatorium treatment was given. In the third case there was a cavity in the right upper lobe and the sputum was crowded with tubercle bacilli; the patient's general condition was good, and the cavity contracted when sanocrysin was given. The weight dropped during treatment but rose subsequently. Sanatorium treatment followed and a relapse occurred. After another course of sanocrysin good health returned and was still persisting, though albuminuria, which had commenced during the treatment, was still present. The fourth case was characterized by a very irregular temperature, and there were definite lesions in the upper half of the right lung; these were cleared up by sanocrysin. The patient refused sanatorium treatment and returned home; at first the improvement was maintained, but more recently a slight chill had followed and the sputum was again found to contain tubercle bacilli. Another course of sanocrysin was therefore started. Sanocrysin was found useless in a bad pneumonic case; no harm was done other than the production of a rash and albuminuria. Professor Cummins thought that sanocrysin gave rise to definite improvement, but that repeated short courses would be found to be necessary. Examination of the sputum showed that it tended to the destruction of tubercle bacilli in the body, and he illustrated this point by several charts of cases. He then gave a short account of animal investigations which had produced evidence that there was definite improvement in the lungs following the use of sanocrysin in rabbits infected with human strains of the tubercle bacillus. He believed that one of the chief uses of sanocrysin would be raising the hospital type of case to the sanatorium level.

Professor F. R. FRASER gave a general account of his investigations and the conclusions he had reached. He had treated fifteen cases of tuberculosis, and one case of lymphatic leukaemia had been used as a control. Two cases were non-pulmonary, and two others had combined abdominal and pulmonary disease. He had started with the dosage recommended by the Danish. His first patient, a man aged 30, had had attacks of haemoptysis for eight years, but was in good condition when the treatment started. Tubercle bacilli were present in the sputum, the signs in the lungs were clear, the fingers were clubbed, but there were no signs of any recent extension of the disease. The first dose of half a gram produced no reaction. Three days later one gram was given; nausea and vomiting started later in the day, and the temperature began to rise. During the course there was a great increase in the amount of sputum. On the fourth day the temperature was 104°, there was a morbilliform rash over the body, and albumin was present in the urine. The patient complained of

a metallic taste in the mouth, and felt very ill. By the eleventh day he had quite recovered, but had lost weight. On the next day another dose of one gram of sanocrysin was given. The ensuing reaction was even more severe; collapse occurred, and he remained ill for a week, no further repetition being possible until the twenty-third day, when another injection was given. The following reaction was short and sharp, and the subsequent doses were attended by much milder reactions. At the end of the course no tubercle bacilli were present in the sputum, no râles were heard in the chest, and the radiographical appearance of the lungs had improved. He then went to Frimley, and regained his weight, but the sputum returned and contained tubercle bacilli. He was now much as before the treatment started, but certainly no worse. As a result of this case Professor Fraser decided that such severe reactions ought to be avoided. He concluded also that the unpleasant symptoms were due to heavy metal poisoning, and proceeded to raise the doses more gradually, with longer intervals between them. No dose over one gram was given. The serum treatment had proved disappointing, so it was thought best that the doses should not be so high as to call for its use. In a later case, in which there was recent and active disease extending over both lungs, with steady loss of ground for some months, this smaller dosage was found to be much more satisfactory. The first dose of half a gram gave rise to no reaction; the second injection of three-quarters of a gram produced a slight and transient response. The third dose was therefore reduced to half a gram, and no increase on this was permitted until subsequent doses were without any response. No loss of weight occurred. By the seventh dose the amount of one gram was reached. Seven days were allowed to elapse between all the injections except the first and second, where an interval of three days only occurred. Râles disappeared from the chest, and the tubercle bacilli diminished in numbers. There was some clearing of the x-ray shadows. It had been expected that this patient would continue getting progressively worse, as had been the case before treatment started, but the disease appeared to be checked by the sanocrysin, and the patient was now at a sanatorium. Similar doses and intervals were used in the third case, in which there was extensive disease with excavation at the right apex and slight involvement of the left. The first dose of half a gram was followed by some vomiting, and the second dose of three-quarters of a gram by a little rise of temperature, nausea, and retching, with a slight rash. On the fourth day the râles were no longer heard over the right lung and the resonance had improved. The third dose of half a gram was unattended by any reaction, and the next dose of three-quarters of a gram only evoked a mild response. Nine days later a dose of one gram caused vomiting and retching. Professor Fraser thought that the good result in this case might have been produced equally well had the treatment terminated at the second dose. In another case tuberculous masses around the ovary and Fallopian tube disappeared in a most remarkable manner after the injection of sanocrysin. It was, however, doubtful whether the advantages of the treatment outweighed the dangers. Lower doses, with longer intervals between them, might prove more satisfactory, and the treatment deserved further trial.

Dr. TATTERSALL reported on ten cases, four of which were still under treatment; six patients had had one full course. All the sputums contained tubercle bacilli, and the disease was in the second or third stage of the Turban-Gerhardt scale. All the patients were afebrile at rest, but they were hospital, not sanatorium, cases. Three were of the chronic proliferative type and three of the exudative. Dr. Tattersall had experienced complications in the course of treatment similar to those mentioned by previous speakers. His first case was a girl, aged 20, who had been ill eighteen months, and, in spite of breaking down twice, had a fair degree of resistance. The disease involved the upper part of the left lung and the right apex; there was pleurisy at the left base. She received one dose of half a gram of sanocrysin, followed by four one-gram doses. The tubercle bacilli disappeared, and in six weeks there

was no sputum. Her general condition improved greatly, a troublesome cough ceased, and radiographical examination showed that the lung condition was very much better. In the second case, a girl with twelve months' history of disease, there was widespread disease, and she was losing ground. Five doses of sanocrysin brought about the disappearance of the sputum in five weeks, the lungs cleared well, and the cough stopped. His third case, a man aged 31, had had a "weak chest" for many years, with definite tuberculous symptoms for twelve months. There was dense consolidation at both apices, and scattered areas of disease elsewhere. After five doses of sanocrysin the temperature had become normal, the lung condition cleared with evidence of fibrosis, and the tubercle bacilli were reduced in numbers but were still present. The sputum had lately increased, however. In a lad, aged 18, with the recent exudative type of disease, six doses of sanocrysin had stopped the cough and sputum. A curious feature about this case was that weight had been gained during the course of treatment.

Dr. G. MARSHALL had spent three weeks in Denmark in June and had seen many hundreds of cases. Only one or two Danish practitioners still used the large doses originally recommended by Secker; others were getting as good results from the smaller doses. Disastrous results still occurred in patients with short histories, and it seemed as though in the early stages of the disease the patient was not in a condition to resist heavy onslaughts of toxins. The use of serum was mostly abandoned, though Secker still employed it. Two patients were known to have died from the use of the serum only, but without any signs of anaphylaxis, and it was obvious, therefore, that this agent was very dangerous. Dr. Marshall gave brief details of his treatment of nine cases of tuberculosis, and of one case of infective endocarditis. The last patient had had a swinging temperature of 103° to 104° for three months. Small doses of sanocrysin were ineffective, but with high doses of two grams the temperature was reduced to normal for several days. Suppression of the urine occurred, however, and, though it passed off, completion of the treatment was prevented by the patient leaving the hospital. The spleen was much diminished in size by the treatment.

Dr. F. R. G. HEAR described the use of sanocrysin at the King Edward VII Memorial Sanatorium, Warwick, and emphasized the importance of commencing with such small doses as one-tenth of a gram. By gradual stages a final dose of one gram was reached, but not exceeded; these doses of one gram were continued over a long period. No severe reactions occurred. He believed that sanocrysin would be found to be of great value in conjunction with collapse therapy of the lungs.

Sir ALMOND WRIGHT referred to his experiments, which had demonstrated that sanocrysin dilutions of 1 in 250 were without effect on tubercle bacilli in blood. He doubted whether it had been shown that the remedy had any real effect on the clinical condition or on the disappearance of tubercle bacilli from the sputum. Similar claims had been made when tuberculin had first appeared. There was no evidence that sanocrysin as a chemotherapeutic agent was able to destroy tubercle bacilli.

Professors ELLIOTT and LYLE CUMMINS replied briefly.

RELATION OF OPTIC NEURITIS TO SINUSITIS.

THE Sections of Laryngology and Ophthalmology held a combined meeting at the Royal Society of Medicine on January 8th, with Sir ARNOLD LAWSON in the chair. The subject under discussion was "Optic neuritis in its relation to sinusitis."

Dr. LOGAN TURNER explained that the present debate was the outcome of the work of a committee which had been formed some time ago to collect illustrative cases and to consider the matter. In each centre where the work was being done the services of a neurologist, a radiologist, and a pathologist had been secured to assist the ophthalmologists and rhinologists in the examination of the cases. He himself was about to present the results of the Edinburgh section. The method adopted had been to collect cases of typical retrobulbar neuritis (excluding the conditions of

syphilis, Leber's atrophy, and the toxic amblyopias) and to investigate the nasal condition in them all. In some of them operations were performed on the nose and the subsequent condition studied, in others the treatment was non-operative. One must not, in attempting to estimate the effect of operation, lose sight of the fact that a large number of cases of retrobulbar neuritis tended to recover spontaneously, and also that some surgeons, over-zealous perhaps, were apt to diagnose and stress a condition known as "latent sinusitis," in which none of the ordinary clinical signs of sinusitis were present. In his series of cases two clinical features stood out—namely, the almost entire absence of complaint on the part of the patient of any nasal symptoms whatever, and the complete absence of any signs of sphenoidal sinusitis on nasal examination. In all but two of his cases (whether operated on or not) recovery took place with restoration of vision to 6/6, 6/8, or 6/12, and this factor of tendency to spontaneous improvement was, he felt sure, of the utmost importance in estimating the effect of operation. Five of his cases were proved to be early cases of disseminated sclerosis; in one the infection was believed to be from the teeth, and in none of these operated on was any pus or evidence of disease found in the sphenoidal sinus. He urged the need for further investigation.

Mr. M. S. MAXON then read a paper on the pathological side of the question. He began by a consideration of the forms of optic neuritis which might be associated with sinus disease. These fell into two groups. In the first group were cases with marked ophthalmoscopic signs, obvious venous obstruction from pressure on the nerve sheath giving rise to the appearance known as "choked disc." In the second group were the cases of so-called retrobulbar neuritis, or, better, "interstitial neuritis." In these the papillo-macular bundle was affected first, and the fields of vision showed a central scotoma. Disseminated sclerosis would serve as a definite example, in which the pathology was well known, of this group. He wished to point out that actual inflammation of the nerve need not be present to produce the clinical picture, since pressure on the nerve would alone be sufficient to cause it. In the first group the pathological findings at *post-mortem* examination were often very marked, cerebral abscess, orbital abscess, and meningitis being sometimes present. He considered briefly the anatomical relations of the optic nerves and the sphenoidal sinuses, and discussed the possible modes of spread of the infection. More light would probably be thrown on the subject if the colour fields were more often carefully examined. Contraction of the field did not necessarily occur. He stated in conclusion that he considered retrobulbar neuritis secondary to sphenoidal sinus disease to be very rare.

Mr. E. D. D. DAVIS then gave a most careful analysis of the results of examination of 76 cases. Of these cases 41 proved on investigation to be due to definite causes, such as syphilis, pituitary tumour, disseminated sclerosis, Leber's atrophy, and albuminuric retinitis. Of the other 35, 5 were associated with manifest nasal sinusitis, while for 30 no cause could be found at all, and nasal disease could certainly be excluded. He considered four possibilities of spread from the sinus to the nerve—namely, by direct extension, by thrombosis of veins, following acute nasal catarrh, and as a toxæmia associated with bacteraemia. He noted that the very severe cases of sinus infection were practically never associated with optic neuritis. In those cases associated with definite nasal signs there were changes in the optic discs, but in the idiopathic cases there were no ophthalmoscopic signs at all. Three of the idiopathic cases were operated on with no improvement. Of the remainder, two subsequently proved to be disseminated sclerosis, five remained stationary, fourteen recovered completely, and the rest were insufficiently examined for a report as to the final condition. In conclusion, Mr. Davis stressed the point that a large proportion of cases tended to recover spontaneously, and he mentioned also that in certain of the idiopathic cases where recovery was retarded operation might be justifiable, as it was unlikely to do any harm.

Mr. FOSTER MOORE said he wished to deal only with

cases of typical retrobulbar neuritis characterized by the presence of a central scotoma, pain on moving the eye, a characteristic pupil reaction, absence of ophthalmoscopic signs, and a tendency to spontaneous recovery. In his opinion an association of this condition with a definite sinusitis was very rare indeed. He did not consider the condition of "latent sinus disease" had any real connexion with the neuritis. Of the large group of idiopathic cases probably a number of them were disseminated sclerosis. In conclusion he said that the frankly septic cases of direct spread to the nerve from the sinus did not give rise to true retrobulbar neuritis, and that true retrobulbar neuritis in association with sphenoidal sinusitis, if it ever occurred, was certainly very rare.

In the ensuing discussion Sir STCLAIR THOMSON cited cases of his own and of Mr. Greeves and Mr. Collins in which operation apparently led to recovery, since the condition had been stationary for some months before operation was resorted to. Mr. TREACHER COLLINS explained that in the case mentioned by Sir StClair papillitis was present, so that it could not be considered a typical case of retrobulbar neuritis. Mr. WILLIAMSON-NOBLE spoke of the possible connexion between the size of the optic foramen and the etiology, and quoted a paper of van der Horst in which it was stated that the foramen was abnormally small in all the cases. Dr. P. WATSON-WILLIAMS considered that toxæmia was more likely to arise if the sinus disease was latent, as there would then be a comparative absence of polymorphonuclear leucocytes and resistance would be less. He was doubtful whether both sinuses were always opened at the operation, and spoke of the difficulty of doing this with certainty.

Mr. GIBB, Dr. LEIGHTON DAVIES, Mr. TRIQUAIR, Dr. JOHNSON HORNE, Mr. GRAY CLEGG, and Mr. WHITEHEAD also took part in the discussion.

PRESERVATION OF FOETAL LIFE.

At a meeting of the Edinburgh Obstetrical Society on December 9th, 1925, the President, Dr. R. W. JOHNSTONE, in the chair, a paper was read by Professor R. P. RANKEN LYLE (Newcastle) on the ethical and scientific aspects of the prevention, conservation, and destruction of intra-uterine life.

Professor Ranken Lyle began by stating that the whole trend of medical thought with regard to the conservation of intrauterine life had been slowly changing during the last twenty-five years, and that the child's life was now considered nearly as important as that of the mother. The intrinsic duty of the medical profession was to preserve and prolong life, from the ovum stage to the death of the individual. Sterilization of patients used to be practised after a single Caesarean section, but in his opinion sterilization was an insult to surgery, and prevented a woman carrying out her mission in life. He himself had only once sterilized a patient after Caesarean section twenty-five years ago, and he had performed that operation as often as seven times on one patient. Induction of abortion for medical reasons ought to be prohibited, as it was contrary to medical practice. In hyperemesis gravidarum hygienic treatment, suggestion, and psychotherapy cured practically all patients, and toxic cases which required abortion were very rare. In tuberculosis pregnancy should be allowed to proceed without interruption; also in cases of heart disease, at any rate until the later months, when pressure was being caused by the growing uterus, and then the question of induction of labour or Caesarean section must be considered; chorea gravidarum very rarely nowadays warranted induction of abortion. Craniotomy on the living child was never necessary, Caesarean section having taken its place, and by this means the maternal, and, of course, the foetal, mortality would be greatly improved. Caesarean section was replacing bipolar version for placenta praevia; the foetal death rate was thus considerably lowered and the maternal death rate was not increased. Even in prolapse of the cord, especially in a primipara, Caesarean section was advocated to save the child's life. Ante-natal care had been instrumental in revolutionizing abnormal obstetrics and in preventing the majority of cases of difficult labour; eclampsia had been checked to a large extent, with a great

saving of maternal and foetal life. Abnormal presentations could now be rectified before the confinement, and breech, face, and transverse presentations converted to normal vertex positions; this allowed many children to be born alive who would have perished if the case had not been under ante-natal supervision. Contracted pelvis could be diagnosed early and the necessary treatment decided upon before labour began, which was a different proposition from seeing the case advanced in labour, when any treatment was likely to be dangerous to both mother and child.

Dr. J. HAIG FERGUSON said that Professor Lyle aimed at high ideals, but sometimes these were unattainable. He did not agree with the non-sterilization of Caesarean section cases, and thought that if a woman had been through the ordeal of three Caesarean sections she had a right to be sterilized if she so desired. With regard to induction of abortion, if the mother's and child's interests clashed the mother should be the first to be considered, and he thought induction should be permitted in some cases of tuberculosis, insanity, diabetes, recent heart disease, and hyperemesis gravidarum. Craniotomy was a repugnant operation, but in domestic practice it was sometimes necessary.

Dr. W. FORDYCE agreed with Dr. Haig Ferguson that the maternal life was the first consideration. He did not think the cases of hyperemesis gravidarum in Newcastle could be quite so severe as they were in Edinburgh, where induction of abortion was sometimes the only treatment that would save the mother's life. Some cases of chorea gravidarum also warranted obstetric intervention. He agreed with Professor Lyle on the question of Caesarean section for central placenta praevia in primiparae. Careful ante-natal treatment would clear away many of the difficulties Professor Lyle spoke of.

Professor B. P. WATSON stated that when an infallible treatment for hyperemesis and other conditions was discovered no foetal life would have to be sacrificed, but at present there were cases that defied all treatment, and in these abortion had to be induced to save the mother's life. With regard to sterilization after Caesarean section, the patient's view must be taken into consideration, and this was especially so when performing the operation for a decompensated heart lesion. There were some cases which warranted craniotomy—for example, a primipara badly lacerated, with a raised temperature and the foetal head jammed in the pelvis.

Dr. JAMES YOUNG expressed surprise at Professor Lyle's assurance that 80 to 90 per cent. of children could be saved by Caesarean section in cases of placenta praevia, and thought it a great argument in favour of such an operation. He agreed with Professor Watson on the value of craniotomy in the definitely septic case.

Dr. FARQUHAR MURRAY (Newcastle) considered that craniotomy was never justifiable on the living child, but on a dead child it might be performed when the head was low down and easily accessible. He urged a fuller discussion in the future on the question of induction of abortion, especially in cases of tuberculosis, and suggested that tuberculosis specialists should be invited to take part.

Dr. G. KEMP PATERSON admired Professor Lyle's high ideal, but doubted if it could be achieved. He thought craniotomy on the living child was still a necessary evil.

THE PRESIDENT said that ante-natal care in the future would help them to realize the ideals of Professor Lyle, but at present there were still some cases which required induction of abortion and craniotomy. Sterilization by deliberate operation was hardly ever justified, but after several Caesarean sections he thought it was often indicated in the best interests of patients.

Professor RANKEN LYLE, in the course of his reply, said that in hyperemesis patients should be treated early before jaundice occurred; up to 1925 he had never induced abortion in such cases, and he had only seen one patient die. Caesarean section, he was convinced, would give better results than craniotomy even in septic cases.

Dr. G. W. LYLE then read a communication on a case of post-mortem Caesarean section in a twin pregnancy with the survival of one child.

A primigravida, aged 25, an albuminuric, eight and a half months pregnant, who had been about twelve hours in labour, was anaesthetized in preparation for the application of low forceps to terminate the labour. Some degree of hydrannia was suspected, but no signs of either maternal or foetal distress were noted. Upon a catheter being passed she suddenly collapsed and died. All attempts at resuscitation having failed, a Caesarean section was performed five minutes after death and a child was extracted. This failed to respond to treatment, but when preparing to close the abdomen fully ten minutes after the mother's death a second child was discovered. This was at once removed, responded to prolonged treatment, and left hospital quite well ten days later.

DEEP X-RAY AND RADIUM THERAPY.

At a meeting of the Chelsea Clinical Society on December 16th, 1925, with Dr. SRYMOUR-PURCE in the chair, a discussion on deep x-ray and radium therapy was opened by Dr. W. L. WATT.

Dr. Watt stated that deep therapy radiations caused direct cell destruction, the chief effect being on the nucleus. Complete obliteration of every individual cell was the ideal towards which all treatment was directed; the tumour then simply disappeared. This happened in many different conditions, such as in parotid tumours, in hyperplastic glands, in sarcomas of bone, in fibroids, in hypertrophy of the prostate, and in carcinoma of all parts of the body. Less complete treatment might lead to incomplete cell destruction, with an apparent loss of malignancy; this was commoner than the ideal result. In a third group in which there was a mixture of cell concussion, effects, together with what might be termed cell concussion, the tumour diminished for a varying period and then began to grow again. This type of effect occurred in deep parts, but nevertheless had given increased comfort to the patient. An immunizing factor might be produced owing to antibodies being set free by the destruction of cells. There was no deleterious effect on the corpuscles of the blood nor on the haemoglobin content. It was possible that a serum might be obtained which would be the third link in the curative chain, the first being operation and radiation, and the second the autogenous production of antibodies.

Mr. SIDNEY FORSDIKE had found radium most useful in the treatment of essential uterine haemorrhage, and patients suffering from this condition had been cured by one application in 90 per cent. of the cases. Repetition of the application might be necessary. In the treatment of carcinoma of the cervix radium was most useful, and might be combined with deep x rays. In some cases this form of treatment in his hands had given better results than an operation, but for early cases operation, in his opinion, was still the best form of treatment.

Dr. HERMAN-JOHNSON said that the evolution of deep therapy had been going on for ten years. He objected to the phrases "cancer dose," "sarcoma dose," and "lethal dose." He thought that tissues became "stale" as regards their response to any given treatment, and that when a patient ceased to respond to deep x rays a course of ultra-violet treatment should be adopted, after which the use of deep x rays might be beneficial. A good result might be obtained by any one of several procedures, the one unpardonable sin being overdosage.

Dr. C. E. INEDELL thought that the actions of x rays and radium were very similar. In a typical case of cancer of the breast, for example, both treatments could deal with the discharge, bleeding, and pain, and reduce the size of the swelling to such an extent that the patient looked forward to cure. Unfortunately, however, both x rays and radium gradually, but surely, lost their beneficial action, and, as a rule, before the swelling had completely disappeared. Deep x rays, and radium after an operation, had undoubtedly effected cures in some cases. One advantage of radium was that the patient need not be moved about whilst undergoing an operation without disturbing the patient. He thought that radium was more destructive to the cancer cell than the deep x rays.

Mr. CECIL ROWNTREE spoke hopefully of the treatment of cancer of the cervix by buried radium needles, and had had good results in this disease as well as in cancer of the tongue.

CAESAREAN SECTION.

CAESAREAN section is an operation which is stated to be the most abused of all operations in America, and in this country also it is probably that the indications for its performance are sometimes interpreted with more width than judgement. It is therefore timely and interesting to have the views on the subject of a British obstetrician so experienced as Dr. HERBERT SPENCER. These views are presented in a small volume entitled *Caesarean Section*. It contains a table of the 120 such operations which he has personally performed at University College Hospital and in private. None of the material in this little book has appeared before, and it is intended as a frank record of personal experience and as a challenge to those who are unable to support his views to furnish full details of their own experiences upon the points raised by him.

Dr. Spencer begins with a brief but interesting historical study in which, among other points, he attempts to trace the name of the operation. "It is not unlikely," he concludes, "that this—the greatest of all operations, as being it directly affects two lives—was called Caesarean, as being too grand to have been first performed on ordinary mortals," though the evidence of any of the Caesars having been thus born is wanting. The indications for the operation in Professor Spencer's series were contraction of the pelvis in ninety-eight cases, myoma in nine, pelvic enchondroma in one, vaginal and uterine cicatrices in three, previous ventro-fixation following myomectomy in one, advanced cancer of the cervix in one, ovarian or parovarian tumours in three, and accidental haemorrhage in four. The author discusses other reputed indications, such as eclampsia, in which resort to it is generally condemned by most obstetricians, placenta praevia, advanced age of the mother, and heart disease, in which last he regards the operation as inadvisable. With the exception of four cases in which the Porro technique was followed (Dr. Spencer regards this as still the best method of operating in the presence of advanced cancer of the cervix), all the operations were of the classical variety. He has not himself tried the lower segment operation, and gives the reasons for his conservatism. In seven cases his operation was combined with panhysterectomy. In twenty-nine cases the operation was repeated—in eighteen for the second time, in eight for the third time, in two for the fourth time, and in one for the fifth time. The total maternal mortality was 3.3 per cent., and the foetal mortality 10 per cent. Dr. Spencer explains in some detail his preference for chloroform as the anaesthetic up to the moment of the child's removal from the uterus; he believes that it prevents the child being born apnoeic. Since being told of this some years ago by Dr. Spencer, the reviewer has practised it in all cases, and can bear out his claims on this point. With regard to the all-important point of sutures, the author is an enthusiastic supporter of carbolized silk, and condemns catgut emphatically. He also condemns out and out the practice of sterilizing a patient on account of contracted pelvis, which he regards as a procedure "justifiable neither by midwifery nor by morals." Others may be inclined to think that in both respects this dogmatic statement is open to argument, and that, while it is essential that such a step should be taken only after careful consideration of all the circumstances and with the full and willing consent of both the parents, there yet remain cases where considerations of humanity make the proceeding not only justifiable but desirable.

The relatively small number of Dr. Herbert Spencer's operations is due to the practice of inducing premature labour in contractions of the pelvis, which is done at University College Hospital about three and a half times as often as over a period of three years works out at 5.5 per 1,000. Dr. Spencer quotes the statistics of the Rotunda Hospital, Dublin, where the figure is 5.1 per 1,000, and also that of Potter (of version fame), whose record is 88 per 1,000, "a frequency which involves many patients in unnecessary

¹ *Caesarean Section*. With a table of 120 cases. By Herbert R. Spencer, M.D., B.S., F.R.C.P. London: John Hale, Sons, and Danielsson, Ltd. 1925. (Demy 8vo, pp. 71; 5 figures. 6s. net.)

risk and is not calculated to bring about that advance of obstetrics which is the avowed intention of that author." We observe, however, that in four recent hospital reports which happen to be at hand, the figures for the St. Mary's Hospitals, Manchester (1924), work out at 117 per 1,000, with a maternal mortality of 3.6 per cent.; those of the Liverpool Maternity Hospital (1924) at 110 per 1,000, with a maternal mortality of 1.07 per cent.; those of the Jessop Hospital, Sheffield (1924), at 57 per 1,000, with a maternal mortality of 2.4 per cent.; and those of the Edinburgh Royal Maternity Hospital (1923) at 37 per 1,000, with a maternal mortality of 3.7 per cent. Dr. Herbert Spencer's figures are therefore strikingly low. This raises the question whether the present generation of obstetric surgeons (and we use the words advisedly) have the same experience of and faith in the natural processes of labour, especially in cases of contracted pelvis, as those who, like Dr. Spencer, have a longer experience dating back to the time when this operation in particular was more dangerous.

Enough has been said to show the scope of this book, whose importance is not to be measured by its size, and it is to be hoped that in so far as it is a challenge it will be taken up by those who have possibly a larger personal experience of the operation. It is perhaps unnecessary to state that it is written with all the author's well known lucidity and dogmatism, and that the various points are made with an emphasis which suggests a characteristic degree of gusto. The literature of modern British obstetrics is unquestionably enriched by such a frank and full statement.

OSLER, McCRAE, AND FUNK'S "MODERN MEDICINE."

THE third edition of *Modern Medicine*, originally brought out in seven volumes by the late Sir WILLIAM OSLER and Dr. THOMAS McCRAE in 1907-10, and revised and reduced by them in the second edition (1913-15) to five volumes, is now coming out again under the editorship of Professor McCrae, with the assistance of Dr. ELMER FUNK. The first two volumes of this third edition are now published²; the first contains about 250 pages less than the corresponding volume in the second edition, and though it is not stated how many volumes the present edition will consist the omens point to more than five volumes. The late Sir William Osler's introduction to the original work in 1907, which was omitted from the second edition, is now reproduced verbatim, thus providing a valuable record of the position of medicine as it appeared eighteen years ago to a broad-minded leader, and in the main being as much to the point as it was then.

As before, Dr. Ludwig Hektoen contributes an introduction to the study of infectious diseases, and the rest of the first volume, with the exception of some twenty-five pages by Professor Homer Wright on mycoses, is devoted to bacterial diseases, the diseases of doubtful or unknown origin, which in the last edition came in the same volume, being dealt with in the second volume. Twenty bacterial diseases are described, including a new article on tularaemia and one on scarlet fever, which has now been transferred from the category of doubtful origin on the ground that it is due to a haemolytic streptococcus; both these articles are by Dr. Elmer Funk. Tularaemia, like melioidosis, of which there is a short account, is an infection of rodents and is communicated to man by the bite of the horse-fly. The mode of transference of melioidosis is unknown, but it may be through food contaminated by rats; its mortality is very high, for out of fifty patients two only recovered. The article on the important subject of the pathology of tuberculosis, formerly written by Professor W. G. MacCallum of the Johns Hopkins Hospital, is now contributed by Dr. Allen K. Krause of the same school, who has made this subject so eminently his own. Dr. F. T. Lord's account of influenza is fortified by statistics and information derived

from the experience of the pandemic of 1918, and probably with wise caution the vexed question of the relation of the influenza bacillus to the disease is left open. The account of undulant fever, originally written by Sir David Bruce, is again revised by Dr. G. C. Low. In the article on meningococcus infections, including cerebro-spinal fever, which is illustrated by four out of the seven coloured plates in the volume, Dr. W. W. Herrick says that he has never seen haemorrhages in the retina in a routine examination of three hundred cases at all stages—a clinical investigation which must compel admiration. The article on diphtheria has been revised by the senior editor, who summarizes the application of the Schick test.

The second volume, about the same size as the first, begins with the diseases of doubtful or unknown origin, such as small-pox, measles, typhus, rheumatic fever, Rocky Mountain spotted fever, and trench fever. Protozoan infections, spirochaetal infections (a new heading), diseases due to animal parasites, diseases due to physical agents and to chemical and organic agents, are then considered in turn, and the volume closes with a new section devoted to the deficiency diseases pellagra, beri-beri, scurvy, and rickets; of these, the two former were in the previous edition included under the heading of diseases due to chemical and organic agents, while the other two were described among the diseases of metabolism. There is a new article on yaws by Dr. Lewis A. Conner, who has also revised the account of syphilis written by the late Sir William Osler and Dr. J. W. Churchman. Yellow fever has now, as a result of Noguchi's discovery of the causal *Leptospira icteroides*, been transferred from the category of unknown etiology to that of spirochaetal infections, and has again been thoroughly revised by the senior editor; spirochaetosis icterohaemorrhagica and rat-bite fever are described by Dr. Elmer Funk, who has also provided the account of diseases due to physical agents—namely, heat-stroke, the bad effects of altered atmospheric pressure, and of electricity. In a new and thoroughly up-to-date article on food poisoning Professor Ernest C. Dickson of the Stanford University Medical School, who has done much outstanding work on botulism, considers the subject under the three headings of poisoning by foods inherently poisonous, bacterial food infections, and bacterial food intoxication, which is synonymous with botulism, as the latter is the only form of food poisoning in which a bacterial toxin has been proved to be the responsible cause of the symptoms and morbid changes. During the period 1904 to 1923 inclusive there were in America 126 recognized outbreaks of botulism, and of the 429 patients 280, or approximately 65 per cent., died; as the intoxication is of limited duration and there is not any new formation of botulinus toxin in the body, the patient should be supported until its effect has subsided and given intravenous injections of the antitoxin at an early stage. Dr. Edward Jenner Wood's article on pellagra contains interesting historical references dating back to 1762, and shows that from 1907 to 1915 it was common in the United States, and then gradually got less, so that now it has become rare in many States of the Union. For historical and other reasons it is appropriate that rickets, "the English disease," and scurvy should be in the capable hands of Professor G. F. Still and Dr. Robert Hutchison respectively.

In conclusion, these two volumes belong to the best type of medical literature, and there can be no doubt of their success; this forecast rests on wise editorial care displayed, including the selection of the contributors. The editors must be cordially congratulated on the results of their labours, and especially the senior, Professor T. McCrae, who in the last six months has also brought out the tenth edition of *The Principles and Practice of Medicine*.

THE HISTORY OF HUMAN ANATOMY.

It was said of Macaulay that, when he reviewed a book, he dismissed his author with a few words of praise or blame, and then drew on his own resources entirely for his review. However that may be, it is certain that no man can review Dr. CHARLES SINGER's book entitled *The Evolution of Anatomy*³ without referring constantly to its

Kimpton, 1925. (Roy. 8vo. Vol. I, pp. xxxii + 845; 7 plates, 51 figures. Vol. II, pp. x + 851; 4 plates, 106 figures. Six volumes and desk index, sold in sets only, 42s. net a volume; 412 12s. a set.)

³ *The Evolution of Anatomy*. By Charles Singer, M.A., M.D., D.Litt., F.R.S. London: Regan Paul, Trench, Trubner and Co., Ltd. 1925. (Demy 8vo, pp. xii + 203; 117 figures, 22 plates. 12s. 6d. net.)

luminous pages. For long we have been well acquainted with the extensive knowledge, the scholarship, and the unflinching enthusiasm of Dr. Singer, and the history of medicine and science already owes him a large debt for what he has accomplished in that particular field of research. But although we have followed his work with admiration, we have sometimes been oppressed with the fear that he might become submerged by the opulence of his learning to such an extent that his humanism would become obscured by his scholastic attainments. But in his new volume we discern a new spirit in which Dr. Singer, without sacrificing any of his great learning, has taken full advantage of the humanist ideals, and has produced a noteworthy book from which the learned, the casually acquainted, and the uninitiated may equally derive pleasure and profit. This we deem to be a great advance, and we look forward with pleasure to more work from Dr. Singer in the same strain, now that he has broken with the tradition of the "schools," and has shown himself to be the holder of such a vigorous and descriptive pen. To emphasize what we mean, we would direct readers to the opening paragraph of the fourth chapter, which has nothing of dreary scholasticism about it, but is conceived in the finest spirit of lofty humanism.

Now, it is a surprising fact that anatomy, the foundation of the biological sciences, has had to wait until the present time for the historian capable of writing in bold hand the gradations through which the science progressed until its destiny was accomplished. It is true that some half-hearted attempts have been made to do justice to a great subject, but the result has been disappointing. Dr. Singer does not carry the history of anatomy further than the epoch of Harvey, when the dawn of its application to physiology was just breaking, nor does the period he has chosen permit him to deal more than briefly with the extension of the boundaries of the subject of anatomy until it embraced histology and physiology—an extension which took definite shape towards the end of the seventeenth century. He foreshadows, however, the prospect of a continuation of his story at some date, when he hopes to deal with the final results of anatomical study—when the evolution of the subject had so progressed that it embraced both physiology and other allied sciences. We shall then have a complete picture of this evolution of the science of anatomy, and that picture will serve the great purpose of asserting the fact that physiology and its subdivisions, though constantly regarded as definite and distinct subjects, are in fact the worthy children of anatomy their great father.

Perhaps in the picture of the evolution of anatomy, as presented by Dr. Singer, the features of uninterrupted progress are too strongly drawn, and we should have preferred greater insistence upon those "stationary periods" which succeeded almost every important advance in the knowledge of the subject. But as a whole the picture is truly and admirably drawn, and can be accepted as an authoritative account of the rise and progress of the science of anatomy.

It is only in recent years that the history of science has received adequate attention at the hands of those qualified to speak concerning the subject, and this book is a shining example of the way in which such work should be done. We recommend all who desire to acquire a knowledge of the history of anatomy to accept it as a safe guide.

FACIAL SURGERY.

IN the preface to his book *Facial Surgery* Mr. H. P. PICKERILL, whose work in dental research is already well known, apologizes for putting the cart before the horse—that is, for describing the methods and technique for plastic surgery before discussing the surgery of the lesions to be treated. But in fact no such apology is needed. The possibilities of facial surgery opened up by the wonderful work carried out at Sidcup are entirely dependent on plastic surgery, and the author himself was one of those who out of an apparently hopeless welter of sepsis

and injury evolved rational and successful methods of treatment. Asepsis and apposition are the watchwords for the surgeon, and for the patient—patience. Some of the results are almost too good to be true, but there is no gainsaying the photographic records, and when every allowance is made for artistic pride the results stand out as triumphs of surgery of which the British school may well be proud.

But it is not as a record of war work that this book claims most attention. Its value lies in the chapters devoted to conditions occurring in everyday life. The methods evolved through the necessities of war can be used to mitigate many conditions of civil life, and of these the author makes an excellent showing. The results of injuries and burns, of operations for tumours, of specific infections, of facial paralysis, offer a wide field for plastic surgery, but perhaps the most hopeful field lies in hare-lip and cleft palate. Not unjustifiably does Mr. Pickerill say that "The operations for hare-lip and cleft palate may, I believe, also be entirely revolutionized," and the chapter on this subject alone justifies the book. The successful use of Thiersch skin grafts in restoring an obliterated buccal sulcus, and of "tube" grafts to make good lost portions of the lip, are points on which the author claims originality, and on the results of which he may be congratulated.

The whole book breathes a healthy optimism, and the general surgeon, as well as the ophthalmologist and the dental surgeon, will find these notes (for the book is commendably brief) on facial surgery both stimulating and practical.

VISCERAL NEUROLOGY.

A THIRD edition of Dr. F. M. POTTSER's *Symptoms of Visceral Disease*,⁵ which has previously been reviewed in these columns (1920, ii, p. 881; 1923, i, p. 109), has given the author the opportunity of broadening the scope of his message by considering the neuro-cellular reaction rather than the nervous reaction alone, and of altering the arrangement of the different parts of the work. In order to bring out the broader conception just mentioned, a new chapter has been written on the relation of the ionic content and physical state of the cell to activity and nerve stimulation, and to this addition attention will be directed. As before, the work is divided into three parts, but what was formerly Part III, the vegetative nervous system, now, with the new chapter just mentioned, becomes Part I, and the former Part I, the relationship between the vegetative nervous system and the symptoms of visceral disease, and the former Part II, innervation of important viscera with a clinical study of the more viscerogenic reflexes, now follow as Parts II and III.

Eppinger and Hess's well known conception of the two morbid conditions of excessive irritability of the sympathetic (sympatheticotonia) and of the parasympathetic (vagotonia) is accepted, though too much stress is thought to have been laid on the effects of drugs, such as adrenaline, atropine, pilocarpine, and physostigmine, in differentiating these antagonistic states of the vegetative nervous system. The underlying cause of this disturbance in the equilibrium of these two mechanisms is a matter for speculation, but recognition of the effect of the ion content of the cell upon nerve activity and the dependence of the ions upon the permeability of the cell membrane and its electrical discharge suggest to the author that the entire neuro-cellular mechanism must be taken into account in explaining the nerve response, and also the need of investigating the metabolism of calcium, potassium, sodium, and magnesium. In this connexion the influence of the endocrine glands on calcium metabolism naturally attracts attention. From investigation of supposedly vagotonic syndromes, such as anaphylaxis, serum disease, urticaria, asthma, hay fever, and eczema, and their relation to calcium, the author concludes that, although calcium must not be regarded as a panacea, it exerts a favourable influence on all purely vago-

⁴ *Facial Surgery*. By H. P. PICKERILL, C.B.E., M.D., M.S. With an Introduction by Sir W. Arbuthnot Lane, Bart., C.B., M.S., Edinburgh: E. and S. Livingstone. 1924. (Sup. roy. 8vo, pp. xvi + 352; 255 figures, 21s. net.)

⁵ *Symptoms of Visceral Disease. A Study of the Vegetative Nervous System in its Relationship to Clinical Medicine*. By FRANCIS MARION POTTSER, A.M., M.D., LL.D., F.A.C.P. Third edition. London: Henty Kimpton. 1925. (Med. 8vo, pp. 394; 85 figures, 10 coloured plates, 18s. net.)

tonic symptoms. It would be natural to have found some reference in this connexion to the work of Drs. H. W. C. Vines and Grove.

The book, as hinted in previous reviews, is somewhat difficult to read, but it deserves consideration in virtue of the manifest thought and labour bestowed upon it.

CHEMICAL ANALYSIS.

THE fifth edition of *Allen's Commercial Organic Analysis* is in course of production, and volume iii^a is now before us. Its subject-matter is hydrocarbons, bitumens, aromatic acids, and explosives. In this volume, as in those preceding it, each section is the monograph of a writer expressly chosen on account of his acknowledged experience of the subject. The adoption of this plan of production was an inevitable outcome of the growth of matter to be included and of the world-wide demand for the book. It is pre-eminently a work of reference for the practical analyst and for the chemist having charge of manufacturing operations. Each section treats at length of the origin of materials and of their production and uses, and contains full descriptions of the particular observations of those who have encountered unusual conditions of quality or character. Nearly sixty pages are devoted to salicylic acid, its salts and derivatives; a very complete account of the characters and uses of these substances is given and of the nature of the impurities they are liable to contain; these impurities are of particular importance in medicine, having been formerly the cause of much inconvenience in the therapeutic use of salicylates. It is a little deplorable to note in directions for analysis a growing tendency towards the style of a cookery-book. That style is perhaps an inevitable consequence of the nature of the information to be furnished, and we may agree that harm only begins when the book is made the source of learning the facts of chemistry instead of serving merely to give directions for the application of knowledge; when that happens the worker is rendered helpless to determine the validity of his conclusions, whenever there is, as must frequently happen, any disturbing factor in the constitution of the sample. Attempts to provide for such difficulties by amplification of the text generally render the context confusing. The writers responsible for the treatise have performed their task with credit. If we may be allowed to bestow exceptional praise on one of them, it is the writer of the section on modern explosives. The volume is a fitting part of the series to which it belongs.

NOTES ON BOOKS.

IN a book entitled *Chronic Disease: A Working Hypothesis* Drs. BACH and WHEELER trace a great many chronic ailments to harmful groups of bacteria within the bowel, and in particular to that ill classified group of microbes the irregular non-lactose fermenting bacilli. The presence of these particular germs is ascribed by the authors to our sedentary occupations and too much cooked food: we need more cereals and nuts. The remedies they offer for the relief of a surprisingly large number of different complaints are, first, a new set of intestinal germs, to be provided by a more rational diet; and secondly, a skillfully prepared vaccine to be administered in a novel way. From the bacteriological point of view the book is disappointing because the authors add nothing to our knowledge of the significance of this particular group of germs and provide no convincing evidence to warrant the bad character they give them. From the clinical point of view we can only congratulate the authors on the success they have obtained by means of a form of treatment which on theoretical grounds seemed to have little to recommend it.

In a thesis for the doctor's degree of the University of Buenos Aires Dr. BLAS L. ITURRALDE discusses complications due to exploratory thoracentesis.⁸ He adopts Cordier's

classification into the syncopal, the convulsive, and the hemiplegic, although in practice the different forms are often associated. The syncopal form is the commonest; it is embraced by 21 of the 31 cases collected by the author; 17 of these were fatal and 4 ended in recovery. Seven examples have been recorded of the convulsive form, of which 4 recovered, though in one psychical disturbances persisted, while in 3 death took place in two to five days. In the hemiplegic form, of which only three cases with two deaths have been reported, the paralysis was transient, lasting only a few hours. Two theories have been put forward to explain the occurrence of such accidents following an exploratory puncture of the chest—namely, that of gas embolism and that of a pleural reflex. In view of the relative harmlessness of entrance of air into the veins, the author rejects the theory of gas embolism, and accepts that of a pleural reflex originating in the rich nervous network in the pleura and transmitted by the pneumogastric nerve to the bulbo-cerebral nuclei. Prophylaxis consists in subcutaneous injection of morphine about twenty-five minutes before the operation so as to prevent the development of the reflex. The thesis contains the histories of 30 cases, 14 of which have been recorded by British writers, as well as one hitherto unpublished which was under the care of Professor Destéfaro and the author.

Dr. WERNER SCHULTZ in the preface to his excellent book on the acute diseases of the pharyngeal tonsils⁹ says somewhat cynically that "the anginas have long been a stepchild. Residents and specialists have until lately divided between them the task of leaving this domain unnoticed, or, if that is saying too much, undeveloped." The book which Dr. Schultz has produced as the result of his study certainly atones for this sin of omission, if indeed his reproach is justified, but he points out with good reason that many of these very acute cases run a course so rapid and difficult to interpret that without an intimate knowledge of their pathology the quick and accurate action required is not possible. The work actually is a complete account, with special reference to pathology, of the inflammations of the tonsil which occur both as local diseases and as a part of such general diseases as diphtheria, leukaemia, the venereal diseases, and the various infectious fevers. If one part in particular merits praise it is that in which the affections of the pharynx and tonsils in blood diseases are described. The illustrations, which are coloured and faithful to life, are excellent, and should there be another book which covers the same subject we will venture to say that it can hardly be better.

The first edition of Dr. EUGEN KISCH's book on heliotherapy, and Bier's method in bone and joint tuberculosis, was reviewed in this JOURNAL four years ago (1921, vol. ii, p. 658), and there is little change in the second.¹⁰ Dr. Kisch still holds that in heliotherapy it is the heat rays and not the chemical rays that cause deep pigmentation, and that, as in Bier's congestion treatment, it is the resulting hyperaemia that is responsible for improvement. With these methods he combines the administration of iodine. If his theory is correct it follows that high altitude stations are unnecessary, for as good results can be achieved by means of the oxy-acetylene lamps which he uses, and even without mercury vapour or quartz lamps. There are a number of figures which appear to show that under such treatment sequestra may be absorbed and the resulting cavities filled by new bone.

The second volume of *Fortschritte der Sexualwissenschaft und Psychanalyse*,¹¹ of which the first appeared nearly two years ago (see JOURNAL, August 16th, 1924, p. 280), has recently been issued under the editorship of Dr. WILHELM STEKEL, assisted by Dr. ANTON MISSENGER and Dr. EMIL GUTHRIE. The volume contains seventeen original articles dealing with such subjects as the relations of narcissism to homosexuality by Dr. Wolfgang Gerster, the dynamics of sado-masochism by Dr. Walter Schindler, the neuroses of pregnancy by Dr. Sándor Feldmann, the psychology of pain by Dr. Stekel, dream analysis by Dr. Marciniowski, and psycho-analysis in general practice by Dr. Zygmunt Siegel; there are eleven shorter communications, including papers on the treatment of epilepsy, impotence, and dipsomania, and medico-literary articles on Martin Luther and Ibsen's *Peer Gynt*; abstracts from current literature and notes on books.

¹⁰ *Knochen- und Gelenktuberkulose; mit Theorie und Praxis der Sonnenbehandlung*. Mit einem Vorwort von Prof. August Bier. II Auflage. Leipzig: F. O. W. Vogel. 1925. (Imp. 8vo, pp. 295; 367 figures, 6 plates. M.40; bound, M.43.)

¹¹ *Fortschritte der Sexualwissenschaft und Psychanalyse*. Herausgegeben von Dr. Wilhelm Stekel. Redigiert von Dr. Anton Misinger und Dr. Emil Guthrie. II Band. Leipzig und Vienna: Franz Deuticke. 1925. (Med. 8vo, pp. iv + 575. 2fs.)

⁸ *Allen's Commercial Organic Analysis*. Vol. iii. Editors: Samuel S. Sadtler, S.B., Elbert C. Lathrop, A.B., Ph.D., and C. Ainsworth Mitchell, M.A., F.R.C. Fifth edition, revised and in part rewritten. London: J. and A. Churchill. 1925. (Med. 8vo, pp. ix + 732; 35 figures. 30s. net.)

⁹ *Chronic Disease: A Working Hypothesis*. By E. Bach, M.B., B.S., D.P.H., and O. E. Wheeler, M.D., B.S., B.Sc. London: H. K. Lewis and Co., Ltd. 1925. (Cr. 8vo, pp. vii + 142 + xi. 7s. 6d. net.)

¹⁰ *Accidentes por puncion exploradora de la pleura*. Por Blas L. Iturralde. Buenos Aires: "Las Ciencias" de A. Guido Buffarini. 1925. (Sup. roy. 8vo, pp. 73.)

A course of lectures given at the Birkbeck College in connexion with its centenary have been published in a book¹² which has a preface by the Right Hon. J. Ramsay MacDonald, and a centenary foundation oration by the Prime Minister, the Right Hon. Stanley Baldwin. The six lectures included in the volume are all on the progress made during the last century in the special subjects selected for review. Viscount Haldane deals with progress in philosophy, Sir William Ashley with evolutionary economics, Sir Michael Sadler with progress in education, Sir Joseph Thomson with progress in physical science, Professor William Bateson with progress in biology, and Dr. G. P. Gooch with progress in historical studies. Altogether it is an extremely interesting collection of essays.

E. MERCK'S *Report on Recent Advances in Pharmaceutical Chemistry and Therapeutics, 1917-1921*,¹³ is an English translation and summary of the volumes of Merck's *Jahresberichte* which appeared during those years. The publication of the German editions has been noticed from time to time. The reports give particulars of experimental and clinical observations on new and important drugs, and the volume under notice contains an account of such drugs as Bayer 205, cocaine, silver salvarsan, novarsol, and hundreds of other drugs on which important work was published during the years with which it is concerned. In view of the interest aroused by sanocrysin it is interesting to note that three pages are devoted to the description of the action of organic gold compounds on tuberculosis and twenty-one references are given to work done between 1915 and 1921. The volume forms a useful work of reference for anyone who desires to find out what has recently been done with regard to almost any new drug.

PREPARATIONS AND APPLIANCES.

The Spiess-Drager Inhaling Apparatus.

Dr. S. D. BHABHA (Inhalation Therapy Clinic) writes that according to Hubener and Huckel of the Pharmacological Institute of Göttingen, the vapour produced by the Spiess-Drager apparatus reaches the alveoli of the lungs, whereas other types of apparatus carry the vapour to the bronchioles only. Microscopic measurements have shown that the average diameter of the vapour particles is 5 to 10 μ , and that it can be further reduced by increasing the pressure of oxygen. With this apparatus drugs which are used internally and hypodermically can be brought into direct contact with the mucous membranes of the respiratory tract and produce a physiological effect with the minimum dosage. Even an irritating drug like iodine can be administered without any disagreeable effects. The apparatus is not designed for giving anaesthetics but for the inhalation treatment of asthma and other diseases of the lungs and air passages.

The apparatus is mounted on an oxygen cylinder, and the inhalant drugs are placed in two glass tubes, one amber colour and the other white; the former is for the use of photo-sensitive drugs. Each of these tubes has a vulcanite nebulizer inserted in it; the oxygen facilitates the nebulizing process and is inhaled with the drug vapour, thus enhancing its effect. The vapour is inhaled through a face mask or through a nasal vulcanite inhaler. The mechanism is such that two drugs, one aqueous and the other oily, can be mixed and reduced to vapour. The oxygen under high pressure is brought to a low working pressure by valve 2; the manometer A indicates the low pressure, while the finimeter B indicates the high pressure.

Before releasing the oxygen from the cylinder, by turning the handle at valve 5, it is essential to see that the regulating handle 2 and the two valves 3 and 4 which control the flow of oxygen into the two phials are all unscrewed. When the oxygen has been turned on at valve 5 the larger handle 2 should be slowly screwed up. When this is done the oxygen will gradually flow and the indicator in gauge A will register the amount that is being used. The usual amount per minute is from 3 to 5 litres. The apparatus can be seen working at the Clinic for Inhalation Therapy, 30, Grosvenor Place, S.W.1. It is very simple, and nurses are easily trained in the working of it.

UNITED STATES VITAL STATISTICS.

In a preface by Professor Winslow of the Yale School of Medicine to a book entitled *The Principles of Vital Statistics*¹ it is indicated that it is intended primarily for the instruction of public health nurses. That is a very modest claim. The volume does not go into the technicalities of statistical methods, the construction of life tables, Poisson's formula, definitions of statistical terms, and so forth, but it gives, in a fashion comprehensible to any intelligent reader who possesses a knowledge of arithmetic and a reasonable amount of common sense, a most valuable account of the statistical facts illustrative of and resulting from the health conditions of the United States. Not only so, but in a concluding chapter devoted to the interpretation of statistics, the subject of errors and fallacies is dealt with clearly and simply by way both of example and exposition.

Owing to the independence of individual States, and the limitation of control over them by the Federal Government, the Registration Area does not embrace the whole population of the Union, but Dr. Falk's data show that it includes 81 per cent. of the total. It may be noted in passing that in the volume the word "data" is used as though it were singular; "data usually appears" and "the data . . . is not typical." Is this an Americanism or an individualism? The distinction between "urban" and "rural" is drawn at the population figure 2,500, any geographic unit under that being rural, and all else urban, but there is a further distinction (p. 165) between cities and urban places. A problem which does not seriously trouble us in this country, either statistically or otherwise, is that of racial differences. The negro population is, of course, the outstanding instance. In the experience of the Metropolitan Life Assurance Company, which takes a scientific as well as a financial interest in all such questions, the death rates per 1,000 of population in the period 1911-16 were, in the white population 11, and in the coloured 17.2, the combined rate being 11.8. The male white death rate was 11.8, and the female 10.4, the corresponding rates for the coloured population being 17.6 and 16.9. Another question dealt with by Dr. Falk is the death rate according to nativity, and the following table, though relating only to a single year and a single State, is worth quoting in full.

Mortality of Persons of Different Nativities Living in New York State in 1910.

Nativity.	Death Rate per 1,000 Persons.	
	Males.	Females.
Native	13.8	12.4
Italian	12.9	13.7
Russian	15.1	12.5
Austro-Hungarian	14.3	12.4
English, Scottish, and Welsh	16.6	15.8
German	17.9	14.4
Irish	25.9	23.5

For the same year and State statistics are given of deaths from tuberculosis, and here Russia comes out best, Ireland occupying the same bad pre-eminence. As regards progressive diminution of the total deaths since the beginning of the present century, it is claimed that the improvement now extends to all ages for the United States Registration Area as a whole, and with trivial exceptions the figures given support this contention. As between the two years 1910 and 1920, there has been, per 1,000 of population, a percentage decrease as follow: All ages 12.7; under 1 year, 26.1; 1 to 14 years, 24.5; 15-44 years, 4.6; 45-74 years, 11.6; 1 to 74 years, 10.5; and 75 years and over, 6.1.

These are merely examples of the valuable contents of the volume, which deals with morbidity as well as mortality, with birth rates as well as death rates, with the census results of 1920, and various other matters. It is freely illustrated by excellent charts and diagrams.

¹ *The Principles of Vital Statistics*. By I. S. Falk, Ph.D. Philadelphia and London: W. B. Saunders Company. 1924. (Post 8vo, pp. 238; 31 figures. 12s. 6d. net.)

THE CONSTRUCTION OF THE SENNAR DAM, SUDAN.

ANTIMALARIAL ORGANIZATION.

LAST summer the work on the Sennar dam and the Gezira canalization was completed, and on July 15th the sluice gates were opened and the water flowed through the canals on to the land. This dam is two miles in length and 107 feet in height at the deepest part of the river. A reservoir 50 miles long is formed above the dam, holding one hundred and forty-four thousand three hundred and seventy-five million gallons of water. The Nile level is raised 50 feet when the dam is full. The area at present under irrigation is 300,000 acres.

The work took five years to complete, and was carried out in a section of the country which during the rains was intensely malarious. This fact was really the crux of the situation, and a description of the sanitary organization that enabled the work to be carried to a successful conclusion will be of general interest.

THE DAM CONSTRUCTION WORKS AND THE WORKMEN'S TOWN.

Makwar was chosen as the site of the new town for the men working on the construction of the dam. The European houses, railway station, hospital, workshops, cement factory, and the workmen's permanent camps were placed on the high ground on the west bank of the Nile about a mile away from the river.

Between Makwar and the Nile a khor or broad depression extends; it is over five kilometres long and half a kilometre broad. In the rainy season it becomes a marsh of alternating thick wood, open water, and long grass, being flooded by the surface water from the higher land and inundated by the Nile at the crest of the flood (see Fig. 1). The higher ground above the marsh was covered during the rains with tall thick grass interspersed with pools and marshy areas. Mosquitos swarmed everywhere in the marsh and higher land alike. The conditions on the east bank were similar, but not so difficult.

In addition to Makwar there were three subsidiary working stations—one wood-cutting and boat-building station in a forest twenty miles south of Makwar, and two stone quarries thirty miles to the west of Makwar and ten miles apart. The medical and sanitary arrangements for these places were controlled from Makwar.

LABOUR.

The labourers employed were for the most part Egyptians, brought up from Southern Egypt for periods of six months, and Sudanese recruited locally. In the season 1923-24, when the work was at its height, the labour roll reached 19,000.

The Sudanese possess a certain limited degree of immunity to malaria, but it is insufficient to prevent them from being largely incapacitated unless they are adequately protected from the disease. The Egyptians, on the other hand, are very susceptible to malaria, and need most careful protection.

About 70 British engineers, foremen, clerks, and crane drivers were employed, and working under them were a large number of Italian stone cutters, Greek foremen, mechanics, Egyptian clerks, Maltese engine drivers, and Egyptian artisans. In addition 200 Italian stone cutters were employed at the quarries.

SANITATION.

The special sanitary objectives were mainly three: (1) The prevention of malaria by the elimination of the mosquito, by the screening of dwellings with mosquito-proof wire, by the segregation of the partially immune Sudani from the non-immune Egyptian labourers in camps apart from each other, and by the issue in certain cases of protective quinine. (2) The prevention of dysentery by eliminating fly-breeding spots, by multiplying bucket

latrines, and, where these were impracticable, smoke fire latrines, and thus preventing the dissemination of faecal material in dust or by flies, and by installing a piped water supply. (3) The prevention of the spread of ankylostomiasis by the detection and treatment of all cases among imported Egyptian labourers at the Wadi Halfa quarantine station.

A British medical inspector was placed in charge of the medical and sanitary work, and a British sanitary inspector was appointed to assist him in the conservancy and anti-malarial work at Makwar and the outlying stations; a mosquito squad of Sudanese worked directly under the British sanitary inspector. A hospital with accommodation

for 120 patients was built at Makwar. Two Syrian medical officers assisted the medical inspector at the hospital and in the medical supervision of the staff and labourers. First-aid stations were organized at various parts of the works and at the outlying stations.

Antimalarial Works.

The first step was to drain the higher ground on which the houses and workshops had been built through the marsh to the river. Grass and bushes to a

depth of 100 metres from the houses were cleared. Later the marsh itself was drained, bushes and scrub cleared, and the holes filled in. The deep drains through this marsh into the river were protected by sluice gates, and when the Nile rose above the level of these drains the water was pumped out by petrol pumps. As the river flood occasionally rose above its banks at this point a strong earth embankment was constructed along the river bank for a distance of three kilometres. By means of these works, which were gradually

FIG. 1.

FIG. 2.

CONSTRUCTION OF THE SENNAR DAM.

carried out over a period of years, the principal mosquito breeding grounds were abolished.

Quarantine Station at Wadi Halfa.

A quarantine station was opened at Wadi Halfa, the northern frontier station of the Sudan, and all labourers from Egypt were detained there for thirty-six to forty-eight hours. The very old, the very young, those unfitted for hard work by organic disease or profound anaemia, and those suffering from fevers, active syphilis, or other infectious diseases, were rejected. The remainder were deloused and their clothing and belongings were disinfected. They were also examined for bilharziasis and for intestinal parasites, and particularly for ankylostoma parasites. All cases of ankylostomiasis were treated. Nominal rolls were prepared giving details of each labourer, and sent with them to their destination. There they were again treated for ankylostomiasis.

The quarantine station was capable of passing 500 labourers through in two days, and in emergencies this number could be increased to 600. The largest number of labourers passed through this station in one year was 14,336, and the total number for the period 1919 to 1925 was 45,029. No cases of typhus or relapsing fever occurred among Egyptian labourers after they had passed through the quarantine.*

For oiling pools, etc., the most efficacious and cheapest larvicide was found to be heavy crude engine oil. Pegs wrapped round with sacking soaked in this oil were stuck in the pools, and the oil continued to exude slowly for four or five days, and so kept up a continuous film.

General Results.

The results obtained are shown in Table I. It will be seen that there was a progressive decrease in the malaria rate as sanitary precautions were more completely elaborated, but the risk of a malaria outbreak was always present.

TABLE I.

Season October 1st to September 30th.	Average Monthly Number Employed.	Malaria.		Dysentery. Percentage Attacked.	Enteric Fever. Percentage Attacked.	Rainfall in mm.
		Percent- age Attacked.	Death Rate per 1,000.			
1919-20	Egyptians 840	33	31.0	2.3	—	403.5
1920-21	Egyptians 2,555	8	1.9	3.1	—	343.4
1921-22*	Egyptians 1,375	2	1.5	0.6	0.25	477.7

* Work closed from the end of March till December 1st, 1922.

Table II gives the number of mosquito infections found in collections of water each year. As the construction work spread over a larger area on both banks of the river each year, so the ground covered by the mosquito squad increased.

With the drop in the number of cases of malaria there was a fall in the number of subtertian infections. For the

* A detailed description of the organization of this quarantine was given by Major B. Spence in the R.A.M.C. Journal, November, 1924.

period 1919-21 the prevailing type of infection was subtertian. For 1922-23 benign tertian was the prevailing type. In 1923-24 only one case of malignant malaria was admitted to the hospital, and during the following year there was not a single case of subtertian malaria.

Prophylactic Quinine.

This was not given as a routine measure, but only in special cases where it was essential that the work should be carried out in malarious places and where the length of stay did not warrant extensive antimosquito precautions, etc. The following example points to the value of prophylactic quinine in special cases: 170 Egyptian labourers were employed in the Sagadi quarries during the rains. A count taken before the rains began showed that 3 per cent. of them had enlargement of the spleen, and they were all put on 10 grains of quinine daily. Only two out of this number fell ill with malaria, while the two British officials in Sagadi, who lived under very much better conditions but did not take quinine daily, both had attacks of malaria.

CANALIZATION OF THE IRRIGATED AREA.

This involved the digging of the main canal from the dam to a point 35 miles to the north, where the first branch canal takes off, and the complete canalization of an area of 300,000 acres. The canalized area is approximately 52 miles long, with an average width of 12 miles. The main canal is 71 miles long. There are 711 miles of branch canals and 8,750 miles of subsidiary canals and feed channels.

The sanitary control of this area was a more difficult problem than that of the dam construction area at Makwar, as the employees and workmen, instead of being collected into one main centre and three subsidiary centres, were divided into small groups scattered over a wide area.

Work was started on the main canal in 1920, but it was not until January, 1923, that the detailed canalization was begun. At this date the number of mechanical excavators worked by British drivers was greatly increased, and in addition 8,000 natives, of whom half were Egyptians, were employed. The sanitary control of the area now became very difficult. The labourers were split up into gangs and were scattered over the whole area; the gangs were constantly changing ground, and it was difficult to keep in touch with them. Each of these gangs had to be supplied with water from the river; the water was pumped into small canals, which had to carry it in some cases over twenty miles.

The control of these water canals was a matter of great difficulty; the native drivers in charge of the pumps did not know when the carrying capacity of the canals had been reached, and water oftentimes continued to be pumped long after the canals were overfull. A messenger dispatched to inform them would arrive three or four hours too late. As a result bursts were frequent and considerable areas of low-lying ground would be flooded. Inspection even by car was slow and difficult owing to the canalization cutting across the old roads and tracks.

At the commencement of the rainy season the Egyptian labourers were sent back to their homes, but the British drivers continued to work the excavators on the minor canals. Sudanese labourers were also working on the minor canals. During the rains miles of partially excavated canals became filled with water, and during this season it was impossible to get about the country except on a few main roads, so that matters had to be left as they were till the rains had ended and inspection once more became possible. It was then a race to get the canals pumped out or treated with larvicides in time to reduce the mosquitoes before work began again.

MEDICAL AND SANITARY ORGANIZATION.

Wad Medani, a large town situated about the centre of the canalization area but on its eastern edge, was made the centre for the sanitary and medical organization of this area, and the hospital there was considerably enlarged to meet the increased work.

Two subsidiary centres were established—the one at Hag Abdulla, the southern end of the canalization area, and the other at Kilo 114, to the north-east of Wad Medani. Small temporary hospitals were built at these centres to deal with minor cases. In addition six mobile dressing stations were established, each consisting of a reliable hospital attendant, with a bell tent, a box containing drugs and dressings, and a donkey for transport.

Two motor ambulances were allotted to this area, and were stationed at the northern and southern centres. They brought in the milder cases of sickness or injury to the subsidiary centres, and the more severe cases they took direct to Wad Medani hospital. From Wad Medani they brought back the recovered cases, and also drugs, dressings, and larvicides.

The medical and sanitary organization of this area was directly under the charge of a British medical inspector detailed especially for this work. He was centred in Wad Medani, and had a car at his disposal. He inspected every working party at least once in ten days, seeing that they were in good health, adequately fed, and that the sanitary conditions were satisfactory. He also frequently visited the British drivers in charge of the large mechanical excavators, and the British and European engineers and overseers.

The medical inspector was assisted in the sanitary work by a British sanitary inspector, who was provided with a motor lorry for transport. With this, while on his inspection work, he was able to take small gangs of mosquito men or labourers to any point where they were urgently needed, and to replenish the central dumps with larvicides from Wad Medani. The mosquito brigades made a complete inspection of their sections once in ten days.

The condition of the workmen as regards malaria and general health showed progressive improvement as these arrangements were elaborated. In the early months of 1924, however, it had become impossible for the sanitary gangs to keep pace with the widespread leakage of water and the consequent mosquito infections. A sharp epidemic of malaria occurred, which threatened to bring the work to a standstill. Certain sanitary recommendations with regard to mosquito control and transport of mosquito gangs, which had been neglected in the high pressure of work, were at once carried out, and the outbreak died down and there was no further epidemic. The malarial incidence among all workers for 1924 and 1925 was 5 and 4 per cent. respectively. These percentages cannot compare with the Makwar figures, but the area, though less naturally malarious, was more difficult to control. The workmen as a whole were maintained in a high degree of health efficiency.

Careful watch was kept on the local population for fear that they should become infected with bilharzia from the Egyptian labourers. Frequent inspections of the villages have been made, but up to the present there is no indication that this infection has occurred.

We are indebted to Dr. O. F. H. Atkey, Director of the Sudan Medical Service, for the information on which this article is founded.

PREVENTION AND TREATMENT OF TINEA CRURIS IN BOYS' SCHOOLS.

In 1925 the Medical Officers of Schools Association was invited by the Headmasters' Conference to appoint representatives to meet them to discuss the subject of tinea cruris and to suggest measures for treatment.

A special committee, consisting of Dr. L. R. Lempriere of Halesbury, Dr. N. F. Hallows of Marlborough, and Dr. A. I. Simcy of Rugby, was appointed by the association to draw up recommendations for the Headmasters' Conference. The committee has presented to the Headmasters' Conference recommendations for prevention and treatment, which are here reproduced.

RECOMMENDATIONS FOR PREVENTION.

Tinea cruris is a skin disease caused by a vegetable parasite which is apt to occur where adolescents and adults live in close quarters. It is probably spread by dust and by garments and

towels which have become infected. It is certainly much more prevalent in the community at large than is generally supposed. It chiefly affects the groins, armpits, and toes, but if neglected may appear elsewhere on the body.

We recommend:

1. That to prevent the importation of fresh infection at the beginning of term the medical officer should, at his discretion, obtain the necessary permission to examine all boys in senior houses at the beginning of term, and at such other times as the circumstances may warrant.
2. That where this has not already been done, parents, house-masters, and boys be informed of the nature of the disease and their co-operation sought in the early detection of cases.
3. That boys be instructed to report redness and/or irritation of the thigh. Neglect to do so is a serious offence against the community.
4. That changing-rooms, drying-rooms, and lavatories be adequate for their purpose; that every care be exercised to ensure cleanliness and tidiness after use; and that inquiries be made to ensure that the laundry arrangements in the school are entirely satisfactory from a hygienic point of view.
5. In our opinion the danger of infection would be greatly decreased if pants were worn with cloth clothes throughout the year, and if, where serge shorts are used, bathing drawers were worn underneath them.
6. That O.T.C. uniforms be disinfected whenever a change of ownership takes place.
7. That studies be kept tidy and overcrowding avoided; that curtains, hangings, and draperies be discouraged; that boots, flannels, uniform, and toilet articles be not kept in studies; that any floor coverings used in dormitories be removed and washed periodically.
8. That a period of isolation accompanied by adequate disinfection be carried out as an essential part of treatment in every case.
9. In order that the period of isolation and treatment of tinea cruris be as short as possible, the treatment recommended in the leaflet should be followed.
10. We further suggest that by reason of the length of time often required for the cure of cases during the holidays, and inasmuch as the medical officers of schools have better opportunities for acquiring a more intimate knowledge of the incidence and treatment of the disease than doctors in private practice, a concession be made to parents, allowing infected cases to return for sanatorium treatment at the beginning of term, but to prevent abuse of this privilege, and to protect the authorities against financial loss, the usual home medical fees be charged.

RECOMMENDATIONS FOR TREATMENT.

1. The naked-eye appearance of tinea cruris is usually so characteristic that a diagnosis can be made without microscopic examination. The fungus is not always easy to detect, even in obvious cases of the disease. Experience shows that the very large majority of rashes in the groin area in schoolboys are due to this fungus. The whole surface of the body, especially the axillae and internal cleft, should be carefully examined to determine the extent of the disease at the outset.
2. The case should be isolated at once and kept in bed during sanatorium or bedroom treatment.
3. For at least six days apply thickly spread dressings of either ung. chrysarobini B.P. or ung. ararobae B.P.C. once daily and retain them in position by means of bandages or bathing drawers, or else use liberal inunctions of the same twice daily. Where only one thigh is found to be infected, both must be treated. It is essential to use a reliable and active sample of the ointment (that supplied by the General Apothecaries' Company has been found uniformly good).
4. During the period of treatment in bed the patient should be examined daily.
5. At the end of this period, provided that the applications have been adequate, it will be found that the central infected area has become smooth and pale with a surrounding red line and erythematous band at the junction of the infected and normal skin.
6. When a satisfactory result has been obtained the patient should have a hot bath and wash the affected area thoroughly with soap. (Baths are not advised during the period of treatment.) Clean disinfected clothing is then put on, and the patient may then be discharged as free from infection.
7. As an additional precaution after discharge, ung. ac. benzoici co. B.P.C. should be applied daily to the affected parts for from two to three weeks.
8. It is advisable that boys, after the course of chrysarobin treatment, should be inspected at weekly intervals and should report to the medical officer on return to school.
9. Disinfection is an essential part of the treatment, and should this be inadequate reinfection is almost certain to occur. Towels and all articles of clothing and bedding which may have come in contact with the infection should be either boiled or treated in a steam disinfectant.
10. Desquamation between the toes should be carefully treated whenever it exists, either with the ointments above mentioned or by painting with tinct. iodi fort.

SATURDAY, JANUARY 16TH, 1926.

DIABETES AND PREGNANCY UNDER INSULIN TREATMENT.

THE profound influence of diabetes on the nutrition of the tissues made it fairly certain from the first that the study of the effects of insulin on the resistance of the body to infectious and other stresses would yield much information of value, not only for the elucidation of the individual diabetic patient, but for the importance of the general subject, which is one of the utmost importance to the general practitioner, and that in which his special skill is perhaps most conspicuously shown.

Professor J. A. Nixon has done a service by the review of the present position he gives in the very practical and comprehensive lecture published this week. He illustrates the change which has come over the prospect of the diabetic patient in whom an emergency operation is indicated by an apt quotation from Treves's *Surgery* (1896), and gives sound detailed advice as to the way to use insulin in a surgical emergency. We propose, however, to make here a few observations about another emergency, that of pregnancy, to which also he briefly refers.

The association of true diabetes and pregnancy has always been a cause of grave anxiety. It is never a very common combination, because the diabetic state produces changes which militate against the occurrence of pregnancy; but when pregnancy did occur in a diabetic woman in pre-insulin days the outlook was gloomy for both mother and child. The foetus not infrequently perished and was born prematurely, and in a large proportion of the more severe cases, the mother also succumbed. It is quite true that in some instances, as stated by Whitridge Williams, Joslin, and other experienced observers, spontaneous improvement occurred in the mother's condition in the later months of pregnancy; but a relapse followed after delivery. Recent experimental work upon animals indicates that this may be explained by the fact that the pancreas in the foetus is able to supplement the functions of the maternal organ, although the actual passage of the pancreatic internal secretion has never been observed. Such supplementary action on the part of the foetal pancreas could only occur after the islands of Langerhans have developed, and this in human foetus occurs about the fourth month of gestation. Accordingly, any beneficial action could not be expected until the last few months of pregnancy. Such experiences are, however, by no means uniform, and more frequently the mother's condition became gradually worse as pregnancy went on.

Evidence is now accumulating in regard to cases of diabetes and pregnancy treated with insulin, and the general conclusion seems to be that careful dietetic treatment combined with adequate administration of insulin may so modify the diabetic condition as to make the prognosis decidedly more favourable than in the pre-insulin days. We recently published an abstract (*Epitome*, November 14th, 1925, para. 441) of a paper by Hennberg and Bickel to this effect, and an even more

successful and instructive case was reported recently to the Académie de Médecine by Marcel Labbé and Couvelaire.¹ Their patient was a woman of 32 with a strongly diabetic heritage, who had become diabetic at the age of 27, during her second pregnancy. After delivery the disease continued to progress, and she became seriously emaciated. When the third pregnancy occurred she was advised in Athens to have abortion brought about as soon as possible. However, she came under the care of the authors in Paris, and they determined to try the effect of rigorous dietetic treatment and insulin, more particularly as she was very anxious to have another child. For the first few months the patient carried out the treatment conscientiously, and the improvement was all that could be desired. But about the sixth month her natural appetite overcame her, and she broke all her dietetic rules, with a resultant serious relapse. There was marked acidosis and an associated rapid increase of the quantity of the liquor amnii, which threatened of itself to necessitate the interruption of pregnancy. The danger of the situation was explained to the patient, who promised faithfully to behave better, and a resumption of the rigorous treatment was followed by immediate improvement. It is interesting to read that the condition of hydramnios disappeared *pari passu* with the condition of acidosis and the general improvement. In this way the patient was tided safely up to the time of the confinement, which was normal and resulted in the birth of a healthy, well developed child. The puerperium was normal, and the patient regained her usual strength and weight, while the diabetic condition subsided to the level at which it had been before the occurrence of pregnancy. One of the most interesting features of this case is the fluctuation observed in the patient's condition according as she did or did not observe the rules of treatment.

More clinical records of similar cases are required, and it may be confidently expected that where the insulin treatment is started early and is carefully and adequately carried out the results will be successful. The diagnosis of true diabetes is a matter of importance in this connexion in view of the now recognized possibility of a temporary lowering of the renal threshold to sugar in pregnancy. Blood sugar estimations and the presence of typical symptoms are the essential criteria.

SEXUAL OFFENCES AGAINST THE YOUNG.

No kind of wickedness arouses the anger and disgust of our fellow-countrymen more than sexual depravity when this takes the form of assault upon the body or mind of a child. The sensational way in which the trials of such cases are sometimes reported tends perhaps to obscure the general feeling of detestation, but of its reality there can be no doubt. Anything, therefore, that can be done by statute or procedure to safeguard the young from this evil, to care for those who have suffered, and to deter the wrongdoer, will be welcomed by public opinion. The subject was debated in the House of Commons two and a half years ago, when attention was drawn to these offences, and to the prevalent belief that those who committed them were often mentally abnormal. Early in 1924 conferences were held at the Home Office at which persons representing various organizations interested in the matter were present. The outcome of all this was the appointment by the Home Secretary in the

¹ Bull. de l'Acad. de Méd., November 17th, 1925.

following July of a committee to investigate the prevalence of sexual offences against young persons in England and Wales, and to consider any measures that might be taken to prevent their occurrence.

The Departmental Committee's report,¹ of which a copy has just reached us, is in the nature of things a document of sociological rather than medical interest, and the recommendations (no fewer than forty-three in number) are for the most part legal and administrative. But the subject has medical bearings, direct and indirect; for the state of mind, and the physical state too, both of the person accused and of the child, are very often an important factor in such cases. This aspect of the inquiry was acknowledged by the appointment of a medical member of the Committee—Dr. A. H. Norris, Chief Inspector of Reformatories and Industrial Schools under the Home Office—and it was emphasized by the inclusion among the seventy-five witnesses of ten medical men and women with special experience in one direction or another. So far, therefore, as the problem concerns our profession, it may be supposed that the medical point of view was adequately put forward, though we cannot speak with certainty as to this because, for reasons of economy, the evidence is not printed with the report.

The Committee's terms of reference were "to collect information and to take evidence as to the prevalence of sexual offences against young persons and to report upon the subject, indicating any direction in which in their opinion the law or its administration might be improved." On certain points, we learn, there was striking unanimity among the witnesses; on others, as might well be expected, the evidence was most conflicting; and on one (the question of whipping as a punishment) the Committee was itself as divided as those who appeared before it.

Many of the Committee's recommendations will no doubt receive general approval. Everything possible should, of course, be done to protect the interests and the feelings of young persons before, during, and after the hearing of these unsavoury cases, and the detailed proposals regarding administration of the law and provision for child welfare seem wise and practicable. The same may, we think, be said of the recommendations for expert mental examination of offenders and for prolonged detention of those who offend again and again. While the injured child is naturally its first and chief care, the Committee recognizes, in so many words, that the offender too has rights. It is aware also that among its forty-three recommendations are some that "may appear somewhat drastic at first sight." Presumably the Committee has in mind its proposals for changes in the law, which include raising the "age of consent" to 17, and abolition of the defence by a young man of 23 or under that he had "reasonable cause to believe" that a girl was 16 or over. The difficulty here is one that always lies in the path of would-be reformers of the penal code: the means may defeat the end. Multiplying offences and stiffening penalties may in the long run swell the number of acquittals; experience proves that too severe laws lead to soft verdicts and light sentences. The chairman of the Committee, Mr. J. C. Priestley, K.C., and Mr. T. W. Fry (Metropolitan Police Magistrate) and Sir Guy Stephenson (Assistant Director of Public Prosecutions) are evidently well aware of this hard fact, for the report, though signed by all the members, is followed by a cogent memorandum, signed by

these three, dissenting from the recommendation in favour of raising the age of consent to 17 years. Mr. Fry and Sir Guy Stephenson also put in a memorandum dissenting from the recommendation that the defence of "reasonable belief" should be abolished. On the other hand, another member, Miss E. H. Kelly, signs a memorandum arguing that the age of consent for a girl cannot be considered apart from the raising of the age of criminal responsibility for a boy, and that in each case it should be 18.

The report is drawn up in nine sections. The first consists of some preliminary observations, from which one passage may be quoted, since it indicates the Committee's evident desire to take a wide view of its responsibilities: "A difficulty which has been present with us throughout our deliberations has been to reconcile measures which are in the best interests of the young victims of these offences with the essential requirements of the administration of justice. On the one side are the law and procedure which are inevitably and properly framed to ensure a fair and impartial trial, and which entail formality and publicity and the necessity for strict legal proof. On the other side are children who, on account of their immaturity, are unfit to be associated with courts of justice, and for whom, on account of the nature of the wrongs they have suffered, publicity may be harmful in the extreme." The second section deals with the prevalence of these offences, from which it seems fair to draw the inference that on the whole they are not on the increase, more especially when the growth of population is borne in mind. The next three sections are devoted to procedure before trial and the administration of the law. Section six deals with matters relating to the offender, who for some reason or another is assumed throughout to be invariably a male, and we cannot find a word in the report showing that sexual offences are sometimes committed by women against boys and youths, though the Committee expressly states in regard to the victims of sexual offences that its recommendations and suggestions are directed towards the care and protection of boys as well as of girls. Section seven is concerned with the welfare of young persons involved in trials for sexual offences, and with methods for the control of adolescents who persist in undisciplined habits of life. The eighth section indicates certain improvements in social conditions which, in the Committee's view, should lead to a better moral standard, and thus tend to diminish the occurrence of sexual offences. The concluding section gives a summarized list of the recommendations scattered throughout the preceding pages.

DEATH OF MR. BASIL HALL.

WE have to announce with the deepest regret the sudden death, on Tuesday morning, January 12th, of Mr. John Basil Hall, M.Chir.Cantab., F.R.C.S., consulting surgeon to the Bradford Royal Infirmary, and immediate Past-President of the British Medical Association. At the Autumn Dinner, held in October last at the Association's new House, Mr. Basil Hall was the principal guest of the evening, when he was welcomed on returning safely from his tour of Canada and the United States as the representative of the Association; and less than a month ago he was among us again, apparently in excellent health, at the December Council meeting. All who attended the Bradford Annual Meeting in 1924 will remember how largely its success was due to the genial personality of the President. We hope to publish a memoir in our next issue.

¹ Report of the Departmental Committee on Sexual Offences against Young Persons. Cmd. 2561. London: H.M. Stationery Office, or through any bookseller. 1925. 2s. net.

RUTHERFORD MORISON TESTIMONIAL.

It will be remembered that last year a committee was formed at the suggestion of the Newcastle-on-Tyne Division of the British Medical Association to raise a fund for a presentation to Professor Rutherford Morison in recognition of his great services to the medical profession, especially in the North of England. As part of this it was resolved to present Mr. Morison with his portrait in oils. The portrait has been painted by Mr. Harold Knight, and will be presented to Professor Morison by Professor H. Brunton Angus on behalf of the subscribers at a meeting to be held at the College of Medicine, Newcastle-on-Tyne, on Thursday next, January 21st, at 4 p.m. It is hoped that as many subscribers as possible will attend.

CONTINENTAL SURGERY IN 1818.

EXTRACTS from the diary of a young Dutch surgeon when on a visit to Belgium, France, and Germany more than a century ago have recently been published, and are now translated into English by Joseph Bles.¹ The writer of the diary was Dr. C. B. Tilanus, who was afterwards professor of surgery at the University of Amsterdam, having only succeeded in shaking himself free from obstetrics, with which surgery was combined, after years of patience. In those days of dirty surgery the union of the two chairs was a great misfortune for the lying-in woman, and it may have been some alleviation of her lot that the professor took no interest in practical midwifery. Tilanus, who was accompanied by two other young surgeons, made his way to Brussels, but after a short stay there the party went on to Paris, then the Mecca of surgical pilgrims, for Dupuytren and Larrey were at the height of their fame. What with sepsis and free and frequent blood-letting, the Hôtel-Dieu at Paris appears then to have been as deadly as it was some years later, and until Listerism changed its ways. The three young Dutchmen seem to have taken little interest in anything but operations, and apparently Dupuytren gave them plenty of *tours de force*, followed in nine cases out of ten, perhaps, by *post-mortem* examinations. Strangulated hernias seem to have been submitted to operation only when gangrene was at hand, and the results were generally fatal. Much praise is given to Dupuytren for his skill and daring, but nothing is said of the desperate courage of the patient who submitted to the "long and difficult" operation of resection of the lower jaw—of course, without an anaesthetic—only to die a week later of sepsis. We are told that Dupuytren did not think that the *post-mortem* appearances accounted for the death. Dupuytren's treatment of fractures is described. In one case of fracture of the forearm splints were applied so tightly that gangrene and necrosis followed, and the patient died. But Dupuytren was "*chirurgus incomparabilis nemini secundus*." From Paris the trio went to Strasbourg, and, chiefly on foot, visited sundry university towns in Germany, where they met various celebrities, such as Chelms and Nägele, and examined curiosities and natural history and other museums. It is worthy of note that at Marburg in Hesse, Professor Bünger "believes in sutures made of gut, and thinks they are absorbed. at least, he noticed this in a calf (which he showed us) after tying the *carotis* and cutting the ends of the suture" (from the context it is obvious that for "suture" we should read "ligature"). This anticipation of one of Lister's great innovations was rendered valueless, no doubt, by the prevalence of infection in open wounds. At Cassel they were shown the museum by Professor Matsko, who warmly resented their criticisms, but was not above accepting two thalers for his pains.

His salary was so small that he had to make what he could in this way. Tilanus had a long and successful career in Holland, but even he could not see far into the future of surgery, for at the jubilee meeting of the Society for the Advancement of Surgery, in Amsterdam in 1840, he said that though surgery "was not quite perfect it was within measurable distance of being so." At that time surgical anaesthesia was not known in Holland. We may not laugh at such confidence; it should rather make us sad to think that there are improvements in the womb of the future of which we do not dream. The translator of this interesting little book is unfortunately not familiar with the English equivalents of Dutch and Latin technical terms, so that we are occasionally left in doubt as to his meaning.

CHARLES DICKENS.

It is more than ninety years since *Sketches by Boz* appeared, and half as long ago since their author died, yet the fame of his works and the interest taken in his personality, and even the trivial details of his life, are probably as great as ever they were, if not greater. Writing a few years after the death of Dickens, Anthony Trollope said he was "probably the most popular novelist of any time"; and Trollope was by no means a blind adorer, for he adds: "To me it almost seems that I must be wrong to place Dickens after Thackeray and George Eliot, knowing as I do that so great a majority put him above those writers." Even Sir Walter Scott has not had such a huge and enthusiastic circle of admirers. We are prompted to make these reflections by the receipt from the Dickens Fellowship of the coming-of-age number of *The Dickensian*, the organ of that society, which this month completes its twenty-first year of publication. The fellowship has its branches all over the English-speaking world, and to judge by their reports they are vigorous and flourishing. Last year it acquired the house in Doughty Street in which its hero lived, and has opened it as a museum of Dickensiana and a meeting place for Dickensians. In this coming-of-age number there is an article on Tavistock House in which the paper on the site of the Association's new house which Mr. Muirhead Little contributed to our issue of July 18th, 1925, is freely drawn upon, and some of its illustrations reproduced with due acknowledgement. Among several other articles of interest is one on "Those wonderful eyes," in which the brilliancy and colour of Dickens's eyes are discussed and many observers quoted. All are agreed as to their brilliancy, and there is a consensus of opinion that they formed the most striking feature in his face, but the statements as to colour are of a bewildering inconsistency. They range all through the list of possible iris pigments from black to light blue. Carlyle, in a characteristic slapdash statement, in which he described Dickens as very small, said that the eyes were "clear blue." Trollope that they were "not blue; but of a very distinct and brilliant hazel." Marcus Stone, R.A., who knew him well, said that "they were green-grey in colour, an unusual eye." But as this statement was made as late as 1810 it is possible that the artist's memory had played him false; otherwise it is difficult to believe that a man of his training and intimate knowledge of Dickens should make a mistake, as seems to have been the case. This wide diversity of evidence affords food for thought as to the descriptions and identity of persons wanted by the police, whose eye-colour is always recorded with unflinching definition. The colour of the iris in Frith's portrait, now in the Forster collection at the Victoria and Albert Museum, is distinctly brown, such a brown as goes with the sitter's hair, but it is remarkable how little of the iris is clearly visible owing to dilatation of the pupil. In the portrait by Ary Scheffer, now in the National Portrait Gallery, also

¹ *Surgery: A Hundred Years Ago*. Extracts from the Diary of Dr. C. B. Tilanus, afterwards Professor of Surgery at the University of Amsterdam. Edited by H. T. Doelman, Professor of Pathology at the University of Groningen, Holland. Translated from the Dutch by Joseph Bles. London: Goldrey Bles, 1925. (Ct. 8vo, pp. 156; 20 plates. 6s.)

the eye is brown; but, on the other hand, the much praised portrait by Maclise, which hangs in the same room, has distinctly grey eyes. So much do painters differ in their interpretations of their own perceptions. The impression of brilliancy and darkness of eye is mostly conveyed by a wide pupil, a fact said to be appreciated by ladies who enhance their attractions by the use of belladonna. An eye with a dark brown iris and a pin-point pupil will seem lighter than one with a light grey iris and a widely dilated pupil. In our experience it is the slightly prominent eye with the brown iris, clear cornea, glistening conjunctiva, and wide pupil which seems the brightest, and these, as appears from the portraits, were characteristic of Dickens's "scintillating" eye.

OFFICIAL SURGERY.

If we give expression to the surmise that the present generation will not attain to the summit of moral perfection, it must not be inferred that we fail to appreciate or desire to belittle the determined efforts of America to effect the "moral uplift" of mankind. People, in this country at least, are slow to assimilate new ideas, and of this tendency no better instance can be cited than the comparative indifference with which the teachings of those two great schools of American thought, chiropractic and osteopathy, have been received by the medical profession here. Although the doctrine of those schools has been widely preached for a generation or more, no convert was to be found in this country until very recent times; the representatives of the cults were all imports. In the face of this failure to impress the British medical profession, it would appear that a change of policy has now been thought desirable, and it has lately been decided to sow the good seed on less stony ground. The intention is to appeal to our legislators, and it is hoped that they, though necessarily less informed, and conceivably for that very reason, will more readily see the light and make confession of the innate futility of orthodox medicine. We refer to this matter in order to make the suggestion that our legislators, while they are engaged in discussing the project of grafting certain American ideas on to our medical system, should take a broad outlook and include in their view other institutions as deserving. There is, for instance, the School of Official Surgery of Chicago, which would seem to deserve consideration. The director of that establishment, who signs himself master of surgery and doctor of medicine, expressly states that there is nothing of the nature of faddism about the school teaching, and that one of its main objects is, as we might expect, the "uplift" and the training of "bigger, broader, better" physicians. The name adopted for the school appears to indicate that, in pursuance of this laudable aim, the several orifices of the body have been chosen, not inappropriately, as the basis of study. It means, the director says, "an inside view of life." We do not wish to suggest that his school is more deserving of attention than the numerous other institutions of an analogous kind with which the United States of America abounds; we feel sure that our legislators would derive instruction and amusement from the study of any of these institutions—if they have time to devote to such matters.

SMOKE, FOG AND SEA FOG.

THE Meteorological Office of the Air Ministry, through its advisory committee on atmospheric pollution, has issued its eleventh annual report.¹ It deals with observations made during the year ending March 31st, 1925. There are now forty-eight observation stations, an increase on previous years. It is satisfactory that the Midlands area, which suffers most from smoke pollution, is taking a very

active interest in the investigations. But many parts of the country are unrepresented. There are no stations in Wales, and none south of Kingston-on-Thames. Elaborate tables are given of the records for the year. The rainfall was higher than the average in most stations, while the deposit of tar was lower. There was little difference in the deposit of sooty matter, but the total impurity was somewhat less than the average in most stations. Perhaps the most striking observation is the inclination towards a double maximum of impurity on weekdays, which is absent from the Sunday curves. The times of the peaks are affected by the incidence of summer time. The tendency to fewer hazes on Saturdays and Sundays in the last year's curves appears to be due to the fact that factories are usually closed on Saturdays for the half-day and all day Sunday. The first peak of the double wave is due to the factories, the second is due to domestic fires. In the heavy fogs of December, 1924, many observations were made in and about London. At Cheam, eleven miles from London, visibility was less than in London itself; there the fog held much more water in condensation than in London, where there was fifty times as much impurity by weight. It appears justifiable to infer that the "London particular" is formed rather by the replacement of water particles by smoke than by the dirtying of the condensed water by smoke; this appears a reasonable result to expect from the higher temperature of the air over London. A further inference from this observation is that if the smoke of London were materially reduced there would be less liability to fog in London than in the country, for two reasons: first, the heat of the air over the great city, due to the general heating of the buildings, would reduce the condensation of water in the atmosphere; and secondly, the rapid running off of rain from the almost impervious surface of roads and roofs reduces the water in the air due to evaporation. The requisite of suspended matter for the production of fog is well shown in the observations of Dr. Owen off the coast of Portugal. During a sea haze on a bright sunny day the material trapped was almost entirely crystalline. The crystals could be liquefied by heat, and on further warming developed again into crystals. There is little doubt that the crystals consisted of sea salts. Investigations are proceeding on the selective absorption of light by impurity in the air.

THE MOSQUITOS OF EGYPT.

THE recently published report on *The Mosquitoes of Egypt*¹ contains much more information than the title would lead one to expect. At the request of the Antimalaria Commission of Egypt, the author was detailed by the Ministry of Agriculture to undertake a survey of these insects, and was instructed to have it completed within a year. The research worker who is also a capable administrator is a *rara avis*, and the accomplishment of all that is presented in this report is a permanent testimony of the wisdom of the Ministry's selection. Under Mr. Kirkpatrick's guidance three subordinates were relegated to Upper Egypt and three to Lower Egypt, each with his appointed district for collection of specimens, which were sent to headquarters with descriptions of the breeding places in which they had been found. Over 2,000 samples of larvae were thus obtained, and from these more than 30,000 mosquitoes were bred out and identified. After a brief introduction, detailing the arrangements made and enumerating the twenty-two species determined, together with a most useful list of their synonyms, a section is devoted to a systematic study of mosquitoes in general, descriptions being given of the various stages from the egg to the imago, their external and internal anatomy, and their classification. Part III is the application to Egyptian mosquitoes of what

¹ Meteorological Office of the Air Ministry. Eleventh Report of the Advisory Committee on Atmospheric Pollution, for the year ending March 31st, 1925. London: H.M. Stationery Office. Price 5s. 6d. net.

¹ *The Mosquitoes of Egypt*. By T. W. Kirkpatrick, B.A., F.E.S., Senior Entomologist, Ministry of Egypt, Cairo: Government Press, 1925. (Imp. 6vo, pp. xi + 224; illustrated. P.T. 59.)

has gone before. Each of the twenty-two species is fully described, and at the head of each account are given references to the literature which will save future workers an immense amount of trouble, not only those employed in Egypt, but those engaged in similar investigations in other countries in which any of these species is found. Part IV, on the oecology and biology of mosquitos, is of great interest to the general worker. It deals with the variations in their life-history in different climates, with the influence of temperature on their period of development, on their breeding places, and, by the study of the reaction of the various waters, suggests reasons for the presence of certain species in certain districts and their absence from others. It is shown that, contrary to general belief, some species of anopheles inhabit swiftly running streams, that some of the males, and not females only, suck blood, and that females as well as males are phototropic, to name but a few of the interesting questions dealt with. In a subsequent part of the work these points are applied in the consideration of each of the species found during the survey. An excellent instance is given of the apparently uncanny power possessed by mosquitos of avoiding deposition of eggs in places which seemed to be eminently suitable at the time, but which, it was noticed later, dried up before the period of development of larvae and pupae would be completed. There is an instructive subsection on the natural enemies of mosquitos, both in the larval and adult stages. Part V deals with the geography, geology, climate, rainfall, water supply, and so forth, at first in general and then with these conditions in relation to the mosquito fauna. The work of the Suez Canal Company has practically stamped out mosquitos, and therefore malaria, from Ismailia, formerly one of the worst infested parts, but in spite of drainage operations the oases of the Western Desert remain the most mosquito-ridden parts of Egypt. Mr. Kirkpatrick is strongly of opinion that mosquitos are not a necessary concomitant of Egyptian agriculture, and that when antimalarial drainage operations are intended in uncultivated land they should aim primarily at increasing the area of cultivation, control of mosquitos being the natural consequence. The book is furnished with two maps and twenty-four plates, containing 144 carefully drawn figures of various details of the mosquito anatomy, and in fact the whole work not merely constitutes a survey of the mosquitos of Egypt, but certainly merits the subtitle of "a short textbook on mosquitos, a study of their anatomy and life-histories as illustrated by species occurring in Egypt."

THE INVESTIGATION OF THE HUMAN FACTOR IN INDUSTRY IN JAPAN:

IN the report of the Institute for Science of Labour, which was issued at Kurasiki, Japan, in the autumn of 1925, it is stated by the director of the institute, Dr. Gito Teruoka, that the fate of Japanese civilization will be governed by the expansion of its industrial civilization. The number of industrial workers in the country has increased very rapidly of recent years, and it became more and more evident that numerous social problems were being raised which needed special study. To this end Mr. Oohara, the president of a cotton-mill company, founded institutes for agricultural research and for social research, and in 1921 he founded the Institute for Science of Labour. The institute itself is an extensive building of the bungalow type, and contains a large number of small laboratories and office rooms. It has a staff of six investigators, who undertake inquiries in industrial physiology and psychology, nutrition, social hygiene, and industrial diseases. The results of their labours are published quarterly in the Japanese language, whilst the report under review gives a brief account, in English, of some of the main investigations. Most of these investigations were

made at a cotton mill, and the need of them may be gathered from the fact that the operatives appear, as a rule, to work ten hours a day for seven days a week, and to go on to night shift and day shift in alternate weeks. The temperature conditions of the mill must be very trying, for the mean wet bulb temperature ranged from 55° F. in winter to 80° F. in summer. The high summer temperature caused a fall of about 20 per cent. in the output of the workers in the rolling, reeling, and ring-spinning rooms, while the women, when on night shift, regularly lost about 2 lb. in weight during the course of the week, the girls under 18 being specially affected. Numerous observations were made on the body temperature and blood pressure of the workers, but they did not lead to any conclusions of general importance. The chief psychological investigations carried out related to the selection of mill hands. Some 600 to 1,000 persons were subjected to a series of tests which gave a measure of their visual powers and their dexterity, and these tests, after standardization, were used in selecting new applicants. Apparently in consequence of such selection the labour turnover has fallen. The investigations on general social problems are not yet published, but they include biometrical measurements of 8,000 children, and of other measurements on female operatives, in order to determine the effect of industrial work upon growth. Other series of observations relate to mental development and to fertility. Taking the report as a whole, it indicates a promising beginning of a movement towards improved industrial conditions, and it is to be hoped that the investigators will, in course of time, be able to extend their inquiries over a wider range, and include many other industries.

MEDICAL SOCIETY OF LONDON.

THE programme has been issued for the second half of the present session of the Medical Society of London, now, in the 153rd year of its existence. Discussions have been arranged on a variety of topics, some of perennial interest and others that have come only recently into prominence. The first of these debates, on January 25th, will be on manipulative treatment in medicine and surgery, and the openers are two orthopaedic surgeons, Mr. R. C. Elmslie and Mr. W. Rowley Bristow. The second, on February 8th, on pain in the right iliac fossa, will be introduced by a surgeon, Mr. H. W. Carson, a physician, Dr. A. F. Hurst, and a gynaecologist, Dr. T. W. Eden. The third, on February 22nd, on the etiology and diagnosis of gall stones, has been arranged on corresponding lines, the openers being a physician, Sir Humphry Rolleston, Bt., a surgeon, Mr. R. P. Rowlands, and a radiologist, Dr. Robert Knox. The fourth, on March 8th, on obscure pyrexia in adults, will be introduced by Sir Thomas Horder and Dr. C. E. Lakin. The last discussion, on March 22nd, on the use of lead in the treatment of malignant disease, will be opened by Professor W. Blair Bell, Dr. J. G. Adami, and Sir Lenthal Cheate. Each of these Monday evening meetings will begin at 8.30. The three Lettsomian Lectures will be delivered at 9 p.m. on Monday, February 15th, Wednesday, February 24th, and Monday, March 15th, by Dr. E. Farquhar Buzzard, whose subject is "The principles of treatment in relation to diseases of the nervous system." After the annual general meeting on Monday, May 10th, the Oration for 1926 will be delivered by Sir Berkeley Moynihan, and, as in former years, this will be followed by a conversazione. All meetings are held at the house of the society, 11, Chandos Street, Cavendish Square.

To the list of birthday honours published last week (p. 63) should be added the name of Dr. F. J. Willans, M.V.O., Surgeon Apothecary to H.M. Household at Sandringham, who has been promoted to be a Commander of the Royal Victorian Order.

THE SECOND AUSTRALASIAN MEDICAL CONGRESS.

UNDER THE AUSPICES OF THE BRITISH MEDICAL ASSOCIATION,
DUNEDIN, NEW ZEALAND, FEBRUARY, 1927.

WE have received from the Executive Committee in Dunedin of the second Australasian Medical Congress, under the auspices of the British Medical Association (Australian and New Zealand Branches), the following note prepared by Professor Malcolm.

The second Australasian Medical Congress will be held in Dunedin early in February, 1927, and although this notice may seem premature we are anxious to bring the matter before our colleagues at home in order that those who intend to be present may be able to make arrangements in time. We say "at home" because here in New Zealand, probably more than in any part of the Empire, that phrase is commonly used to designate the Mother Country.

It may seem superfluous to say that New Zealand is not a part of Australia, although it is included in that awkward, comprehensive word "Australasia." To many this is indeed well known, but, to practically all who travel so far for the first time, it is a matter of surprise that New Zealand is so far separated from Australia as it is. On the map of the world it seems but a step, and yet it is actually as far as half across the North Atlantic, and in the absence of Atlantic liners the voyage takes nearly as long as from Liverpool to New York.

The shorter route to New Zealand is not by Australia, but either by America, via the Panama Canal, or across Canada (the All-Red Route), or by San Francisco. On the other hand, the Suez and Australia route enables one to see more varied parts of the Empire.

It is not our intention in this article to describe at length, or even to enumerate, all the attractions that New Zealand holds for visitors, but something may be said of the wonderful variety of scenic beauty and other features of interest. From the subtropical regions to the north of Auckland the Dominion stretches south to Stewart Island, the last port of call of those adventurous voyages of discovery to the Antarctic associated with the names of Scott and Shackleton. Because of this wide range of latitude and the varying altitudes, from near sea-level to over 12,000 ft. in the Southern Alps, all sorts of climatic conditions can be obtained, from the cold South to the almost tropic heat of the far North, and from the humid air of the West Coast to the high and dry plains of Central Otago.

The products of this interesting country are as varied as its climatic conditions, and range from oranges, lemons, and subtropical fruits in the North to apples in Nelson and in Central Otago; while in the South the agricultural

products closely resemble those of Scotland—namely, oats, barley, wheat, turnips, etc.

Trout fishing is excellent, and is free to all holders of a licence, a privilege which costs but a guinea a year. Deer-stalking is also under licence, and in certain parts the deer have become so numerous and destructive that Government employs men to shoot them down. The sea-fishing in the North and along the shores of Cook Strait has also begun to attract sportsmen.

By way of scenic attractions the Dominion can show volcanoes, geysers, thermal springs, and other forms of volcanic activity that equal, if they do not surpass, those of any part of the world. In those regions also the

interesting native Maori race can be studied. Partly owing to volcanic activity in the past, the landscape in many parts shows bold natural features covered with native bush, in which the abundant and, in some instances, unique bird life of New Zealand finds its home. Many of the rivers are snow-fed, and flow through wooded valleys of great beauty, such as the Wanganui River and the Rai, Buller, and Otira Gorges.

Both islands have a good rainfall, and the abundant streams supply water for irrigation in certain areas, while in recent years the development of hydro-electric schemes has added to the amenities of life by supplying cheap electric lighting and power. In the South Island are found the famous Southern Alps, where mountaineering, equal to that of Switzerland, may be indulged in. The Mount Cook region is easily reached by train and motor, and the Mount Cook Hermitage provides up-to-date hotel accommodation within easy walking distance of several glaciers, while from the verandah one can hear the rumble of avalanches falling on the slopes of Mount Sefton.

The North Island also has mountain resorts, at Mount Egmont, Tongariro, and Ruapehu.

The south-west coast of the South Island presents features closely resembling the west coast of Norway. While the greater part of this region is as yet unexplored, one of the inlets has been made accessible to tourists.

The famous Milford Track (33 miles) leading from the head of Lake Te Anau to Milford Sound, over the MacKinnon Pass (3,500 ft.), traverses the great belt of forest that is characteristic of the whole West Coast, and leads past glacier-covered mountains and a 2,000 ft. waterfall (Sutherland Falls) to one of the most

beautiful sounds to be seen in the world. During the summer months the track is open for traffic, and the accommodation huts are furnished and provisioned. These are arranged at easy walking stages, so that even children of 12 can accomplish the journey without undue fatigue.

A visit to any one of these three great wonderlands—Rotorua, Mount Cook, or Milford—would be enough of itself to repay the trouble of the journey to New Zealand.

Space will not allow more than brief mention of a few

WANGANUI RIVER.

MOUNT COOK (12,349 ft.).

of the many other scenic beauty spots of the Dominion—Hammer (hot springs and medicinal baths), the Otira Gorge, the Buller Gorge, the Franz-Josef Glacier, where hot springs issue close to the ice of the glacier, Pieton and Nelson, each on one of the numerous beautiful sounds on the southern shores of Cook Strait, the Waitomo Caves (stalactite, with an underground river), Mount Egmont (the Fujiyama of New Zealand), the cold lakes of Otago—Wanaka, Wakatipu, Manapouri, and Te Anau.

During the Congress it is fully expected that the New Zealand Government will give members liberal concessions on the railways. In each of the large towns there is an office of the Tourist Department, where every assistance and information is given. Information about New Zealand can also be readily obtained in London from the office of the High Commissioner in the Strand.

In a subsequent article it is proposed to give some account of the universities and the medical school in Dunedin.

England and Wales.

MATERNITY AND CHILD WELFARE IN NEWPORT, MONMOUTHSHIRE.

DR. HOWARD-JONES, medical officer of health for the County Borough of Newport, in his annual report on maternity and child welfare, states that of all live births in the town during the calendar year 1924 all except twenty-five were duly notified, and that there had been no prosecution for breaches of the Act. During the last twenty years a marked decrease in the infantile death rate during the first year of life has been obtained. In 1904 this rate was 152.9 per 1,000 births, since when it steadily fell to 63.7 in 1922, which was the lowest year on record. In 1923 the rate rose to 64.7, and in the year under review to 72.4. The increased rate was due chiefly to deaths from wasting disease and prematurity, most occurring under one month of age. There was an increase in deaths due to respiratory diseases, and ten inquests on infant deaths were held—the highest number since 1912. The diarrhoea death rate during 1924 was below the average for the last ten years. The maternal death rate of 1.44 per 1,000 births was the lowest since 1904; the corresponding rate for England and Wales was 3.70. Antenatal hygiene is being studied increasingly by expectant mothers and midwives, and 3,004 children between 1 and 5 years of age received treatment. Dr. Howard-Jones remarks that there is a definite need for more voluntary help in the homes during the lying-in period, and for better training of midwives in ante-natal hygiene. More beds are required for infants and young children suffering from defective nutrition and epidemic diarrhoea, and for complicated maternity cases. Arrangements were made during the year for the treatment of orthopaedic cases in conjunction with the Prince of Wales Hospital, Cardiff, part of the cost of the treatment to be recovered from the parents or guardians of patients when possible.

OXFORDSHIRE HEALTH SERVICES.

The Rural Community Council of Oxfordshire has issued a report on the existing health services, statutory and voluntary, in the county. Oxfordshire is not one of the largest counties in England—its population is estimated at 135,180—but the number and ramifications of its health agencies are very surprising when brought together and set forth in consecutive order. The list begins with the statutory authorities—county council, local sanitary authorities, insurance committees, and boards of guardians. The report explains in considerable detail the powers and duties of these bodies, and supplements this by a schedule of particulars. Then it proceeds to the voluntary associations, which it groups under four heads—the medical profession, voluntary hospitals, other voluntary organizations, and financial assistance in sickness. It deals with every hospital, stating the accommodation it provides, its departments, rules of admission, payments by patients, clinics, and so forth. The class "other voluntary organizations"

includes an association for the prevention of tuberculosis, a nursing association, a midwives' association, a branch of the Red Cross Society, and a society for the blind. The report will be most helpful to all in the county who already give, or may by its perusal be stimulated to give, personal or financial aid to the work which is being done. It will be a ready reference book to the benevolent who may know of cases requiring institutional services or trained assistance at home; also, it should be the means of preventing overlapping of work by the various bodies concerned, and, in so far as there may be any incompleteness in the schemes of public helpfulness, it should lead to the supplementing of them. At the same time, we have no doubt that by co-operation and communication the several agencies are protecting themselves against being imposed on by the unworthy, for in every community that is a danger which has to be guarded against. The report is further of value in setting out concisely the ramifications of local health and medical services, and should serve a useful purpose by interesting and educating the public in this aspect of social affairs, the importance of which is emphasized by the provisional proposals for Poor Law reform recently issued by the Ministry of Health. We do not chance to know whether such reports as that issued by the Health Group of the Oxfordshire Rural Community Council are available for many other areas, but if not, then this little manual should encourage the production of such handbooks. We congratulate the Oxfordshire Council on the happy thought which has inspired it to the doing of an excellent bit of work for the welfare of the community which it serves.

Scotland.

EDINBURGH ROYAL INFIRMARY.

At the annual meeting of the Court of Contributors to the Royal Infirmary of Edinburgh, held on January 4th the Lord Provost, Sir William Sleight, who was in the chair observed that during the year a number of extensions and additions had been carried out. These have already been mentioned in the *BRITISH MEDICAL JOURNAL* for December 12th, 1925. The position of the finances of the institution was a great triumph for the advocates of the voluntary system of hospital administration. The total ordinary income was £109,931, an increase of £2,023 as compared with the preceding year. These figures, he said, not only gave testimony to the beneficent activities of their great institution, but were also evidences of the system under which it was carried on, and which he believed the people of Edinburgh were determined to maintain. Negotiations were still taking place with regard to additional ground to meet the ever-increasing needs of the Royal Infirmary extension, and he trusted that an agreement would soon be reached on terms satisfactory to both parties. He expressed regret that the infirmary was not at present able to take in all the cases waiting admission, for the average waiting-list numbered 1,932. Sheriff G. L. Crole referred to the relief of pressure on the wards which would be gained in about two years by the completion of the Astley-Ainslie Institution, which would then be in full operation. Plans were also in course of preparation for Moredun House, and it was hoped that in eighteen months or two years this also would be in full operation. The Court of Contributors elected as its representatives on the board of management for the year 1926 Mr. G. S. Carfrae, Lady Susan Gilmour, Dr. George Mackay, F.R.C.S.E., Sir Malcolm Smith, K.B.E., Mrs. George Kerr, LL.D., and Mr. John Aitchison.

NOTIFICATION OF ENCEPHALITIS LETHARGICA.

The Scottish Board of Health has intimated that from January 1st, 1926, cases of infantile paralysis, poliomyelitis, and encephalitis lethargica shall be notified by the medical practitioners in attendance. The notification is to be made direct to the medical officer of health for the district on the usual form for infectious disease. The

usual fee of 2s. 6d. for notification of infectious diseases is payable to the medical practitioner by the local authority. In cases where the medical officer of health becomes aware of a case suspected to be one of infantile paralysis, poliomyelitis, or encephalitis lethargica, he may take such steps as he may consider necessary or desirable in order to confirm the diagnosis of the case. Notification of infective jaundice, which was compulsory in certain districts during 1925, has been continued for the year 1926.

Correspondence.

THE ULTRAMICROSCOPE IN CANCER RESEARCH.

SIR,—That the microscope has been medicine's right hand in the progress it has made is a statement that will not be questioned, and there will be equal agreement in the admission that there are forms of living organisms so minute that even with all its modern improvements this instrument cannot reveal them to us—they are ultramicroscopic, and the proof of their existence rests solely on their effects. Among these are the filter-passing germs.

This state of matters has naturally led to efforts to improve the power of vision of the microscope, the basis of such attempts being the recognized fact that the limits of that vision depend on the wave-length of light employed. The greatly extended spectrum of rays that science has now put at our command is being utilized in this work, a point well illustrated by the recent researches of Gyo and Barnard. Their investigations seem to show that there are two factors at work in the production of cancer—namely, (1) an intracellular germ, and (2) a "specific factor," whose presence is necessary to enable the germ to exercise its harmful activities. Gyo and Barnard have also demonstrated that although the germ taken from the cancer of one species of animal can be used to produce cancer in another species, the tumour extract of one species will not produce any effect in a different species. They also suggest that in all probability each form of cancer demands for its production its own "specific factor."

In connexion with the germ, a very important piece of work has been done by Barnard, in that he has been able, it is said, to demonstrate it and photograph it by using ultra-violet and even x rays as illuminants in his microscopic work.

It is admitted by all that if the above results receive confirmation by independent investigators a great advance has been made in our knowledge of the actual cause of cancerous tumours. A great deal, of course, hangs on the correctness of the interpretation put on the work done by Barnard with his special apparatus in which he utilizes for magnification the ultra-violet and x rays, which are themselves invisible and do not illuminate objects to the human eye but affect the chemicals of a photographic plate, so that the images of objects unseen by us may be recorded. One asks oneself in this matter if Gyo and Barnard, in coming to the conclusions they have done, have given full consideration and weight to the discovery, by Professor Baly of Liverpool, of artificial photo-synthesis. It will be remembered that he and those working with him found that the very short wave-lengths of the light from a mercury vapour lamp were able to build up formaldehyde from water and carbon dioxide; and, further, by using light with a somewhat longer wave-length the molecules of formaldehyde united to form simple sugars. Under these conditions, it seems to be a possibility that Barnard, by the use of his ultra-violet and x rays, with their short wave-lengths, may have created synthetically new combinations from the materials on which the rays are played, and that he has assigned to these the individuality of germs. Precautions may have been taken to obviate this, but upon this point no information is given in the papers contributed by Gyo and Barnard.

A good deal of stress has been laid on the double factor in tumour growth that Gyo's work has indicated, but this is not a new fact, as Cramer and he have previously demonstrated that the bacterium of gas gangrene is innocuous by itself and requires an accessory substance such as calcium chloride to act as a "catalyst" and

allow the germ to come into play. This, however, is not a feature peculiar to germs; it is seen in the activities where enzymes are concerned, as in the mode and origin of melanin. This pigment, according to Bloch, is due to the interaction within the cell of an enzyme with the mother substance melanogen or chromogen, which has been brought to the cell by the blood and lymph to allow the enzyme to act and convert it into the pigment melanin. Here the enzyme is the "specific virus" in producing the pigment of the cell.

Of late years I have been attracted to the possibility of a pigment being the exciting cause in cancer, and Gyo may yet find that the chemical substance he is in search of is of that nature. I will not go further into this theory, that cancer has a pigmentary origin, as I have fully given my views on this subject in an article published in the *Lancet*, 1922, ii, 655. All I would say is that such a pigment would account both for the cell proliferation characteristic of cancer and for the fact that cancer can only be transferred to a member of its own species. Further, the action of a pigment would explain the excess of unsaturated fatty acids in the fat in carcinomatous areas, an action probably brought about by the cancer cell to allow of the adipose tissue furnishing nutriment for the tumour cells. Consequently, for the solution of the cancer problem, I am inclined to pin my faith more to the pigment than to the ultramicroscope, even with the new and original method of Professor Bechold, which claims by the use of gold chloride to gild bacteria and filter-passers so that ultramicroscopic particles one thousand times smaller than those observed by Mr. Barnard by the aid of the ultra-violet light may be rendered visible. —I am, etc.,

Glasgow, Jan. 7th.

GEORGE THOS. BEATSON.

CANCER OF THE COLON.

SIR,—I have read with much interest Mr. Charles Pannett's paper on cancer of the colon in your issue of January 2nd (p. 1). Mr. Pannett brings out one very important point—namely, that if good results are to be obtained the diagnosis must be made before the onset of obstruction. Fifteen years ago it was very unusual for surgeons to see a case of carcinoma of the colon which was not already complicated by acute, or semi-acute, obstruction. During the last few years, however, thanks partly to improved methods of diagnosis, but chiefly to the greater acumen of the family doctor, quite a large proportion of such cases are now sent to the surgeon before the onset of obstruction. The difference in the operation mortality which has resulted is very considerable, and when we consider that acute obstruction of the colon has a mortality alone, apart from resection of the diseased bowel, of 30 per cent., this is easily apparent. The actual mortality for resection of the colon for cancer, apart from obstruction, is somewhere under 20 per cent.

I agree with Mr. Pannett that no form of cancer gives such excellent operation results as cancer of the colon, both from the point of view of absence of mutilation as a result of the operation and freedom from recurrence afterwards. There is one important point on which I do not agree with Mr. Pannett, or perhaps it would be better to say that I do not agree with what his words appear to mean. Mr. Pannett says that "diarrhoea may occur in addition to the constipation when the growth is left-sided." I would say that diarrhoea is practically always the earliest symptom of a growth in the colon, no matter where the growth is situated. My experience is that the earliest symptom is always intermittent diarrhoea, or marked irregularity of the bowel movements. Although this may seem a small point, I am convinced it is one of very considerable importance, as everything in these cases depends upon early diagnosis.—I am, etc.,

London, W.2, Jan. 11th.

J. P. LOCKHART-MUMBERT.

PUERPERAL MORBIDITY AND MORTALITY.

SIR,—An important fact which emerges from the interim report upon puerperal morbidity and mortality (printed in the SUPPLEMENT of January 9th) is that in more than 60 per cent. of pregnant women the vagina is infected

with streptococci. These can be only on the surface and should be removable by antiseptic douching before labour. This could be done by midwives as well as by doctors, and would probably do more to lessen infection than the system now so strongly advocated of leaving the patient severely alone. If the incidence of sepsis was lessened by this simple means it would go far to prove what many general practitioners have stoutly maintained, that puerperal sepsis is mainly autogenous and is not due to manipulation.—I am, etc.,

Wainstead, E.12, Jan. 10th.

A. CAMPBELL STARK.

SIR,—Sir John Robertson's letter in your issue of January 9th (p. 66) raises points of interest to the general practitioner undertaking maternity work.

He suggests that careful records of the results of maternity cases conducted in special institutions under the care of experienced obstetricians should be collected and published with the object of demonstrating to the profession and to maternity nurses the results of midwifery under good aseptic conditions.

Now surely it is flogging a dead horse rather too obviously to suggest that statistics of confinements under ideal conditions are required to impress upon the practitioner the necessity for that strict asepsis for which he strives in circumstances that are sometimes wellnigh impossible. Furthermore, what remedy is suggested in the compilation of these figures in a case such as Dr. Layton describes when the doctor conducts the giving of the anaesthetic himself, at the same time undertaking an instrumental delivery, with aseptic technique?

Surely there is more at the root of the question of the causation of puerperal sepsis than can be accounted for in terms of operating-room aseptic technique. There is a small but persistent percentage of "septic" cases occurring in private nursing where there has been no manipulation of any kind, and in institutional treatment where the aseptic technique has been flawless. The occurrence of one of these cases when no examination or operation has been made, where there is no reason to suspect any "focal sepsis," and where the case has been watched throughout, is in itself enough to postulate the existence of an *s* factor in maternity that is not related to external aseptic or antiseptic measures of a highly complicated nature.

If such a factor is not admitted, the morbidity of "distinct" maternity work should be something like 100 per cent. and puerperal sepsis in institutional cases unknown. It is surely to the bacteriologist, and possibly even more to endocrinology, that one must look for a reduction in puerperal morbidity, rather than to the perfection of an aseptic technique that, no matter how ideal it may be, can never be practised in its entirety in those homes where the vast majority of confinements still, and will, take place.—I am, etc.,

Harrogate, Jan. 10th.

FAULKLAND L. CARY.

SIR,—I heartily agree with everything in Mr. Comyns Berkeley's article (January 2nd, p. 4) up to the following point: "As someone has remarked, there are two things known for certain about puerperal sepsis: one is nothing, and the other is that the medical attendant will be blamed." If absolutely (not relatively) true, there would seem to be no use for "save the women and children" campaigns and practically no use for interim reports on the subject until we do know something.

Regarding the first point in the quotation above, I think all general practitioners who attend confinements will agree that there appears to be no connexion between "puerperal septicaemia" and "puerperal sepsis." Puerperal septicaemia is without doubt a highly infectious disease commencing soon after labour and occasionally before labour. I doubt if it is known bacteriologically what organism causes it, and more might be done in the investigation of this complication of labour, but no case of septicaemia that I have had in twenty-two years of midwifery work followed undue interference or instrumental delivery, and in two bad outbreaks the infection appeared

to follow in the trail, in one case of the doctor, in the other case of the nurse.

Puerperal sepsis may be caused by the streptococcus or some other germ, and since some part of the genital canal is sure to be lacerated (at any rate in first labours), infection must be a very easy matter, but with ordinary care the risk should be slight, and vaginal douching, and, if necessary, as shown by uterine pain and enlargement, intrauterine douching, can be easily carried out by the medical attendant, and it certainly needs no bacteriological aid to deal with such cases.

Regarding notification, if the rule of reporting all cases with a temperature of 100° F. lasting for over twenty-four hours were instituted it would seem essential to report all cases of whitlow, suppurating sores, mammary abscesses, and every kind of septic condition, as liable to infect some other parturient woman. "Puerperal septicaemia" should certainly be notified, and the nurse and doctor should refrain from attending a further confinement for at least one week. I have certainly seen five deaths follow rapidly from this precaution not having been taken: I do not think either the nurse or the doctor would be blamed if the occurrence was explained to the relatives.

Incidentally, I note that in the interim report of the British Medical Association on the causation of puerperal morbidity and mortality (SUPPLEMENT, January 9th, p. 13) irrigation of the uterus is given last place in the prophylaxis and treatment of puerperal sepsis. It should have been printed in large type at the head of the list and the other remedies in small type.—I am, etc.,

A. H. TERNER, M.R.C.S., L.R.C.P.

Garston, Liverpool, Jan. 10th.

THE METHODS OF INVESTIGATION OF NEO-CARDIOLOGY.

SIR,—Will you allow me to make a few comments on the correspondence, under the above heading, initiated by my letter of November 28th, 1925? I must confess to much disappointment that the simple issues raised by me as to the trustworthiness of the interpretation of the tracings of the polygraph, on the one hand, and the clinical value of the electro-cardiograph on the other, have been practically ignored. As to the former, I pointed out that Professor Starling endorsed (approved) my investigation of this problem in *physiology*; as to the latter, I quoted Sir James Mackenzie ("New outlook in cardiology," BRITISH MEDICAL JOURNAL, January, 1924), to the effect that the electro-cardiograph was of little or no help in determining "the functional capacity of the heart or heart failure." Surely it is of fundamental and primal importance that we should make certain that our interpretation of the records of these two instruments is true and available for clinical use. How, then, is it possible to ignore criticism of modern methods when it challenges the claims of current teaching and practice, and is, moreover, supported by names of such authority as the above?

Dr. Samways, with whom I am in general accord, says that these new instruments introduce "accurate methods"; but of what use is accuracy if we have not the key to the interpretation of the findings? It is a great comfort to learn from Dr. Donald Hall that those who are "familiar with graphic methods" do not relinquish the older methods of heart investigation: but when he proceeds to enumerate the virtues of the electro-cardiograph we find bare assertions, with which we are all too familiar. Indeed, the electro-cardiographer is apt to overstate his case, as when Dr. John Hay (*Graphic Methods in Heart Disease*) says of him: "And he will gradually find that he becomes less and less dependent on these instruments, with which he has served an apprenticeship, for he has learned to do without them. His fingers, his eyes, and his ears are enough in themselves. He has made an advance as a clinician." It is constantly being asserted of the polygraph and the electro-cardiograph that they are instruments of *precision*; is there any science in the world which, having acquired an instrument of precision, proceeds to relinquish it? Dr. L. F. Bishop (*A Key to the Electro-cardiogram*, 1923) quotes the above passage with approval.

The value of the electro-cardiogram in analysing cardiac arrhythmia is generally insisted upon, and Dr. Hall alludes to this; but clinically, as physicians, arrhythmia, as such, concerns us not at all, except it be associated with heart failure—that is, the mechanical failure of the heart to furnish an effective circulation. We are all familiar with cases of delirium cordis (auricular fibrillation type), which through a long life are unaccompanied by heart failure. Such cases are benign, but it is the passage of time which reveals this; other cases, of course, develop a progressive heart failure. Mackenzie's pronouncement, then, is that the electro-cardiograph does not assist us in gauging the all-important functional capacity of the heart as a *power chamber*; herein lies its gravamen.

"A General Physician" deploras the use of the word "neo-cardiology," and he is quite right; let us agree to delete it; but it is the modern school of graphic methods which is responsible for the introduction of the term; witness the title of Sir James Mackenzie's contributions to the *BRITISH MEDICAL JOURNAL*, quoted above. Again, then, let me plead for collaboration in the sifting of this matter; perhaps the younger men coming along, and uncommitted, will bring their fresh energies and open minds to the study and solution of these problems. —I am, etc.,

London, W.1, Jan. 10th.

HARRINGTON SAINSBURY.

* * This correspondence, having served its purpose, is now closed.

HIGH BAROMETER AND SUDDEN DEATHS.

SIR,—It may be of interest to note that so far back as 1732 Dr. Nicholas Robinson published "A discourse upon the nature and cause of sudden deaths; and the reason why such numbers of people died suddenly in the years 1730 and 1731."

"During the year 1730" (he says) "the barometer generally stood at $28\frac{1}{2}$ to $7\frac{1}{8}$. This was occasioned from the moist vapours and dampy Rains that affected the spring, summer and autumn; whereupon the Spring of the Air was extremely relax'd and consequently fitted to produce Palsies, Apoplexies, and Sudden Deaths from a Depression of the Vital Organs beneath the standard of Nature. But in the year 1731, rarely did it fall beneath $29\frac{1}{2}$ " and was often buoy'd up to $29\frac{1}{2}$ inches and sometimes to 30 and $30\frac{1}{2}$; and this was occasion'd from the extreme Dryness of the Season; a Drought so universal as scarce to be parall'd in the Memory of Man. By all this it appears, that the Air was Epidemical in the year 1730 and 1731; and that these sudden Fatal Effects did arise from either the extremes of its sudden Rarefaction or Condensation; which occasioned in the Nerves of the Vital Organs either an absolute Convulsion, or an absolute Palsy, and consequently a sudden Death.

"In the year 1729 there died of Apoplexies and sudden Deaths only 182, but in 1730 although there were 3,000 fewer deaths altogether, the number of sudden deaths swell'd to 238 and in 1731 to 237. To be alive and dead, almost in the same Instant of Time is a scene extremely shocking to humane Nature. . . . To be at once struck off from the List of the Living, is a change very extraordinary, and which must affect the Stoutest Heart with Terror and Surprise."

He goes on to discuss the nature and causes of these sudden deaths. He affirms that the less quantity of blood which animals have, the slower will be their progressive movements.

"There is such a Harmony, Consent and Agreement between the Organs of the Heart and of the Cerebellum, that if an Obstruction or Oppression happens to the one, the other is always affected and exerts a Force and Motion superior to what is Natural in order to remove the Impediment and give a freedom to the oppress'd Organ. In all cases of Paining, if the Brain and Cerebellum did not exert an extraordinary Motion of Systole and Diastole, and immediately detach a considerable Quantity of Animal Fluids to the Heart's assistance, the Patient would assuredly suffer a sudden, fatal Stroke, under every fainting Fit.

"When people fall down dead without the least Struggle, this assuredly happens from a sudden Jerk of the vital

solids, or from a sudden breaking of an Imposthume in the Organ of the Heart, Brain or Medulla. When the Nerves of the Vital Organs are wound up to the highest stretch they can bear, then the least higher Impulse, from either a sudden change in the Air, or setting in to a thorough Debauch, may crack those noble Springs of Life. Such sudden changes in the Air as from Dry to Moist, cold to hot, may lead to a sudden Death." Joy and grief often cause sudden death, but "a great, a generous and a gallant man, bears up in the World like a ship in the sea well-ballasted; so let the Billows rage, the sea roar, and the Madness of the People combine against him, yet he will stand his ground in spite of Fortune, and bear up his Virtue in opposition to the most shocking Ills of Life."

Dr. Robinson was a voluminous writer and practised as a physician in London. He invented a sovereign remedy for the stone, and wrote a "Compleat Treatise of the Gravel and Stone" in 1721; "A New Theory of Physick" in 1725; "A New Method of Treating Consumptions" in 1727; "A New System of the Spleen, Vapours and Hypochondriack Melancholy" in 1729; "Treatise on Venereal Diseases" in 1736; and an "Essay on Gout" in 1755.—I am, etc.,

W. G. AITCHISON ROBERTSON, M.D.,

Bournemouth, Dec. 21st, 1925.

ANAESTHETICS IN CHILDHOOD.

SIR,—Two letters on anaesthetics in childhood (December 12th, 1925, p. 1150) appear to call for some comment. With Mr. Harrison Butler I agree that ether is much safer for eye operations than chloroform, but there are times when ether is contraindicated—such as when the patient has bronchitis or is liable to it—and then the anaesthetist should use his own judgement, for it is on him that the blame will rest if the operation is successful but the patient dies some days later from pneumonia. I am glad to say the surgeons for whom I have given anaesthetics leave the choice of the anaesthetic to me. Ether is in some cases more dangerous than chloroform, and in some a mixture of chloroform and ether is preferable to either, and the anaesthetist should know better than the surgeon what anaesthetic to give.

It is impossible to take Dr. Primmer's letter seriously. First he says he is acquainted with the theory and practice of present-day anaesthetics, and in the same letter refers to Shipway's oxygen and ether apparatus as a "contraption" which reminds him of a mechanical milker. I have used this excellent apparatus—the inhaler, not the milker—for the last five years, and have found it the safest and also the easiest method of giving an anaesthetic. It is especially useful if one has to give chloroform, for the oxygen certainly diminishes the danger. Dr. Primmer is "particularly unfortunate" in quoting this method as dangerous; the explosion he refers to was due to a naked flame, not to Shipway's apparatus, and I hardly like to remind him that ether is inflammable and not "the Shipway." His second statement is that chloroform in the hands of a competent administrator is safe. This is not so; chloroform is a dangerous drug even in the hands of a specialist, much more so than ether. His third statement is that chloroform has stood the test of time. Well, has it? I think not. There are too many deaths due to it every year, and chemists and anaesthetists are still looking for a better and safer anaesthetic than either chloroform or ether.

I have tried to use chloroform wisely, and by that I mean I give it as rarely as possible; whether this is wisely and well is not for me to say; but I would always prefer to use a substitute, and that is ether with oxygen, until a better one is found.—I am, etc.,

ERNEST W. STRANGE, M.D.

Wolverhampton, Dec. 15th.

PALE BABIES AND DEEP PERAMBULATORS.

SIR,—In your issue of December 26th, 1925, attention is called to the improved colour and health of a baby through the raising of its position in the perambulator. There can, I think, be no difference of opinion as to the favourable influence on infants of an increased exposure to sun and

air, in any circumstances and however effected. Dr. Astley Weston has pointed out in a later issue that the particular baby was grossly overfed. Its diet was further entirely ill balanced as compared with the physiological standard—breast milk. Dr. Weston rightly notes that the energy requirements of babies living in the open air are raised, so that they require a more generous supply of calories. It is also true that in an overfed baby enhanced colour may be a danger signal and not a sign of improved health—witness the rosy and beautiful complexioned babies who develop eczema (see A. M. H. Gray, *BRITISH MEDICAL JOURNAL*, December 26th, 1925, p. 1230). In this particular case I think there is probably an improvement.

We are familiar at the Infants Hospital with the pale complexions and toxic-looking appearance of the overfed or wrongly fed infant, and how quickly improvement follows suitable adjustment.

In this case the baby was suffering from a food supply too ample for its energy requirements. Any change, therefore, whether a reduction in food supply or a raising of demand, as effected by the action in question, would assist towards the readjustment needed in the case in question.—I am, etc.,

AMY HONGSON, M.D., M.R.C.P., D.P.H.,

January 11th. Medical Registrar, Infants Hospital, London.

** Professor J. A. Nixon, one of the signatories to the memorandum of December 26th, 1925 (p. 1224), which started this correspondence, asks us to draw attention to a paper by Dr. G. B. Fleming of Glasgow on the theoretical food requirements of infants (*BRITISH MEDICAL JOURNAL*, 1924, vol. ii, p. 1093). Dr. Fleming gives reasons for believing that infants should be given quantities of food suitable for their age rather than for their actual weight. He concludes that during the first year of life infants who are within 30 per cent. of the accepted weight for the age should receive daily a diet of a value of 100 calories per kilo of expected weight. This would be equivalent to about 50 calories per lb.

THE RELATIONSHIP OF THE MEDICAL PROFESSION TO UNQUALIFIED PRACTICE.

SIR.—It was not to be expected that Dr. Manson (*BRITISH MEDICAL JOURNAL*, January 9th, p. 68), even with his unflinching courtesy, would be content with my "general principles" and "philosophic generalities." He is nothing if not thorough. Hence, as of yore, his cry is for the strong arm of the law and for pains and penalties unnumbered and undefined.

His plea is quite to the point. A new offence is to be created—namely, that of unqualified practice—and the alleged offender is to be "haled to the bar of justice." When he arrives there a method not now practised in English criminal procedure is to be applied to him. He is to be "examined and cross-examined," though such forms of discipline are at present restricted to occupants of the witness-box. In a delightful euphemism Dr. Manson names this series of events "the analytic method," and it is indeed a searching enterprise.

Even yet, however, there is a loophole of escape. Suppose that the prisoner-witness, as is possible, refuses to reply. He is now contumacious and mute of malice. Would imprisonment for contempt of court extract his secrets? It may be doubted. In such circumstances Dr. Manson, I am sure most reluctantly, might be driven to a revival of the *peine forte et dure*—that is, the accused must be pressed to death under heavy weights in accordance with a precedent so recent as 1741.

Such may be the inevitable consequences of the "analytic method" when this is applied in all its ruthlessness to the exposure of "pretensions and humbug." Its several stages are: (1) detection of an offender by the medical profession; (2) offender "haled to the bar of justice"; (3) "there examined and cross-examined"; (4) imprisonment for contempt; and, this failing, (5) the thumbscrew, the rack, or even *peine forte et dure*. The collapse of "a soap bubble in the sunlight" is scarcely an adequate figure for so tremendous a programme.

In the meantime I may remind Dr. Manson, while he is waiting for his larger ambition, that it is the right or even the duty of every individual citizen to expose, if he can do so, any fraud which he knows is being practised on the community. It is true that the risk of law courts and actions for libel suggests discretion. But why hesitate at these when the "bar of justice" is welcomed as the most efficient instrument for the triumph of truth and the exposure of humbug?—I am, etc.,

London, W.1, Jan. 9th.

C. O. HAWTHORNE.

CATARRHO-PYOGENIC AND TUBERCULOUS INFECTIONS.

SIR,—May I be allowed to state with what satisfaction and relief I read Dr. Batty Shaw's lecture (December 26th, 1925, p. 1212) putting forward a new nomenclature in connexion with tuberculosis; it is so refreshing to find oneself off the beaten track.

As a bacteriologist I have felt for some years that the activity of tubercle is secondary; that seems to be the only explanation for the fact of tubercle bacilli lying dormant for years, perhaps for life, and only found by chance during a catarrhal cold or else *post mortem*. When examining sputa from various cases one cannot help being struck by the types of bacterial flora found, which seem to bear a relation to the type of case. There is the commonest type with insidious onset and marked catarrhal signs, which usually goes to the bad; this seems always rich in many sorts of bacteria, usually associated with the influenzal group; again, there are cases in which the initial symptoms are haemorrhages, with few if any catarrhal signs, and in these also the bacteria differ.

Is this the key of the puzzle? We hunt for defences against the tubercle bacillus; ought we not rather to tackle the front line first? We all have met cases whose sputa persistently show the presence of tubercle bacilli, and yet seem none the worse and lead useful lives; they obviously have somehow found a clue, but cannot tell us. Perhaps the vitality of the bacilli has been weakened by lack of nourishing soil void of other bacillary toxins.

Of course, we are still left with the problem; yet surely breadth of thought and a readjustment of ideas, as set forward by Dr. Batty Shaw, will all help progress.—I am, etc.,

DOROTHY DALY, B.A., M.B., B.Ch.

Bosford, Wores, Jan. 5th.

Obituary.

EDWARD GRANVILLE BROWNE, M.B.,

F.R.C.P., F.B.A.,

SIR THOMAS ADAMS'S PROFESSOR OF ARABIC; PRESIDENT OF PEMBROKE COLLEGE, CAMBRIDGE.

ON January 5th pneumonia, supervening on other morbid conditions of some duration, brought to a close the life work of Professor E. G. Browne, a phenomenal scholar who, though fully qualified, never practised our profession. His health had been precarious for some time, and the loss of his wife in September last was really his death sentence.

Born on February 7th, 1862, at Uley, near Dursley in Gloucestershire, he was the eldest son of the late Sir Benjamin C. Browne, a member of the famous engineering and shipping firm of Hawthorne, Leslie and Co., Newcastle-on-Tyne, who was Lord Mayor of that city (1885-87), and, being largely responsible for the success of the Royal Jubilee Exhibition and Royal Agricultural Show there in 1887, received the honour of knighthood. The son went to Glenalmond and then to Eton, but his experience was not happy, and in his autobiographical answer to the question so often put to him "What first made you take up Persian?" he wrote: "The most wretched day of my life, except the day when I left college, was the day I went to school. During the earlier portion of my school life I believe that I nearly fathomed the possibilities of human misery and despair" (*A Year among the Persians*, p. 7, 1893). Originally destined to be an engineer, he left school at the early age of 15½ years, partly, at any rate, because the teaching of "the modern side" was then rudimentary.

The Russo-Turkish war in 1877 first attracted his attention to the East, and he became such an ardent admirer of the Turks that his whole ambition then was to become an officer in their army, and with this object in view he plunged with enthusiasm into the language. But his father, who did not smile on the army as a profession, proposed medicine as an alternative to engineering, and as this seemed more compatible with his aspirations he went up in October, 1879, to Pembroke College, Cambridge, and thus began "a new and most happy era of life." He at once studied Arabic under the late Professor E. H. Palmer, the Lord Almoner's Professor of Arabic, thus learning more of Arabic in one term than he had of Latin and Greek during five and a half years; in the long vacation of 1880 he started Persian. In June, 1882, he was placed in the second class of the Natural Sciences Tripos Part I, and in July went for two months to Constantinople as a paternal reward for passing this and the second M.B. The two succeeding years at Cambridge were a period of undiluted pleasure, for his whole time could now be devoted to Oriental languages, and as a result his name was the only one in the first class of the Indian Languages Tripos which included Persian as well as Hindustani, a language from which he "never succeeded in deriving much pleasure." He then returned to medicine by entering St. Bartholomew's Hospital in October, 1884, and came under the influence of Sir Norman Moore, to whom, when President of the Royal College of Physicians, Browne dedicated his FitzPatrick Lectures (1919-20) on Arabian medicine, "in gratitude for his inspiring teaching, and in memory of three fruitful years passed under his guidance." In 1887 he proceeded to the M.B. degree at Cambridge and took also the Conjoint Board qualification; on May 30th of that year he was elected a Fellow, afterwards becoming President (1912), of Pembroke College, Cambridge. It was then arranged that he should come on as house-physician for a year from April 1st, 1888, for Dr. Samuel Gee; but in September, 1887, he went to Persia and did not return until October, 1888, when he went into residence at Cambridge, where in the previous May he had been appointed the first holder of the lectureship in Persian. Accordingly the late Dr. W. H. R. Rivers took his place as house-physician, and, as fate decided, followed him, though in quite another capacity, to Cambridge, where he, too, made a great name.

In 1902, in succession to C. P. H. Rieu, Browne was elected Sir Thomas Adams's Professor of Arabic, and, holding this post until his death, was extraordinarily successful as a teacher of Arabic and Persian. Though he concealed it, he was a most generous benefactor and did much for the Botanic Gardens at Cambridge. In 1903 he became a Fellow of the British Academy. On January 26th, 1911, a new by-law, XL (b), was enacted by the Royal College of Physicians of London whereby "registered medical practitioners not members of the College who have distinguished themselves in any branch of the science or practice of medicine can be elected Fellows," and in the following April Professor Browne and Sir David Bruce were the first to be elected under this by-law. This is an honour carefully considered, and of the thirteen elected in fifteen years eleven are Fellows of the Royal Society, and Professor Browne is the first to leave us. The FitzPatrick Lectures delivered before the College on Arabian medicine were published in 1921 by the Cambridge University Press. This was his main but not his only medical contribution, for in January, 1897, he gave as the mid-session address at the Abernethian Society of St. Bartholomew's Hospital "A chapter from the history of cannabis indica," containing much that was interesting about the assassins and their victims (*St. Bartholomew's Hospital Journal*, 1896-97, iv).

His contributions to the literature of Oriental history and religion were numerous and of a very high order. His great work on Persian literature in four volumes (1902-24) is regarded as beyond comparison the outstanding authority, and contains many admirable renderings of Oriental poetry into English verse. His translation of the Chahâr Maqala ("Four Discourses") (1889) has the special interest that it contains the only contemporary

account of Omar Khayyâm. He also performed a great service in the various accounts of Bábism he published, data for which he obtained after surmounting great difficulties. Among his other works are *A Year among the Persians: Impressions as to the Life, Character, and Thought of the People of Persia, received during Twelve Months' Residence in that Country in the Years 1887-8*; *The Persian Revolution of 1905-1909*, showing his deep sympathy with the Persian reformers, and vigorous detestation of the Russian policy; *An Abridged Translation of the History of Tabaristan*, 1905; and catalogues of Persian and Mohammedan manuscripts. With characteristic unselfishness he completed and saw through the press E. J. W. Gibb's *History of Ottoman Poetry*, of which one volume only of the five was seen by the original author. As a like labour of love he also administered the "E. J. W. Gibb Memorial" which, since its establishment in 1904, has brought out thirty volumes of the texts and translations of Oriental works. As a master of English style his travels are fascinatingly told; he records, like a second De Quincey, how in 1888, from force of circumstance, he temporarily took to opium smoking in Persia. In February, 1921, on the occasion of his fifty-ninth birthday, he received a complimentary address (accompanied by very beautiful presents) signed by a number of representative Persians, expressing their appreciation of his services to their language and literature. He was buried on January 8th at Elswick, Newcastle-on-Tyne, and leaves two young sons, his aged mother, and many friends to mourn his loss.

H. R.

SIR GERALD GIFFARD, K.C.I.E.,

Major-General Madras Medical Service (ret.).

We much regret to record the death of Major-General Sir Gerald Giffard, K.C.I.E., C.S.I., Madras Medical Service (retired), which occurred from heart failure in London on January 5th, a few days before he attained the age of 59.

Gerald Godfray Giffard was born on January 19th, 1867, the son of Agnew Giffard, civil engineer of St. Peter's Port, Guernsey. He was educated at Elizabeth College, Guernsey, and at St. Bartholomew's Hospital, taking the diplomas of M.R.C.S. Eng. and L.R.C.P. Lond. in 1889; also the M.R.C.P. London in 1907. Entering the Indian Medical Service as surgeon on March 31st, 1890, he became lieutenant-colonel after twenty years' service and major-general on July 6th, 1918, retiring on January 10th, 1924. After a few years' military duty he was appointed resident surgeon of the Madras Medical College in 1897, and spent most of his subsequent service at headquarters. In 1899 he became district medical and sanitary officer of Chingleput district, but in 1901 returned to Madras as professor of materia medica in the Madras Medical College and second physician to the hospital. In 1903 he was transferred to the chair of surgery, and in 1906 to that of midwifery. In his first year he served in the Manipur campaign on the north-east frontier of India, gaining the frontier medal with a clasp. Soon after the beginning of the recent great war he was appointed commandant of the Madras War Fund hospital ship *Madras*, and later served as A.D.M.S. of the 6th (Poona) Division of the Indian Army, being mentioned in dispatches in the *London Gazette* of May 18th, 1918.

He received the C.S.I. on June 3rd, 1913, was appointed honorary surgeon to the King on December 29th, 1917, and K.C.I.E. on January 1st, 1923. In 1898 he married the daughter of Mr. James Grose, C.I.E., of the Indian Civil Service, and had two sons and two daughters. Sir Gerald Giffard was for many years a member, and from 1919 to 1923 president, of the South Indian and Madras Branch of the British Medical Association; in 1923-24 he was a member of the Naval and Military Committee of the Association, and also a member of the committee appointed by the Association in connexion with the Royal Commission on the Superior Civil Services in India. At the funeral service at Hampstead Parish Church on Saturday, January 9th, Dr. C. Courtenay Lord, Assistant Medical Secretary, represented the British Medical Association.

Medical News.

THE courses of lectures at the Royal College of Surgeons of England will be resumed on Monday, January 18th, when Professor Sir Arthur Keith, F.R.S., will give the first of six lectures on fossil remains of ape and man, and their bearing on the evolution of human races. Other lectures will be by Mr. Arthur Edmunds, C.B., on pseudo-hermaphroditism and hypospadias and their surgical treatment (February 1st); Mr. J. E. Adams, on the surgery of the jejunum (February 3rd); Mr. Musgrave Woodman, on malignant disease of the oesophagus (February 5th); Mr. Tudor Edwards, on the surgical treatment of phthisis and bronchiectasis (February 8th); Mr. Lawrence Abel, on the treatment of cancer of the oesophagus (February 10th); Mr. H. W. B. Cairns, on neoplasms of the testicle (February 12th); Mr. Stanford Cade, cholecystography (February 15th); and Dr. Alfred Piney, two lectures on the importance of haematology in surgery (February 17th and 19th). The lectures will be given at the College at 5 p.m. on each day.

A NEW series of post-graduate clinics arranged by the University of Sheffield began on January 15th and will be continued on each Friday, alternately at the Royal Infirmary and the Royal Hospital, at 3.30 p.m., up to and including March 19th. On Tuesdays, January 26th and February 23rd, clinics have been arranged at the Jessop Hospital for Women, and on February 9th at the South Yorkshire Asylum. They are open to all medical practitioners without fee.

THE opening lecture of the new series, free to members of the medical profession, arranged by the Fellowship of Medicine will be given on Thursday, January 21st, at 5 p.m., in the lecture hall of the Medical Society of London, 11, Chandos Street, W., by Dr. Herbert Spencer, on abdominal palpation in pregnancy. A course in venereal diseases will take place at the London Lock Hospital from February 1st to 27th. At the Blackfriars Hospital for Diseases of the Skin an afternoon course in dermatology will be held from February 1st to 8th. A three weeks' combined course in diseases of children will be given from February 8th, in which the Paddington Green Children's Hospital, Victoria Hospital, and the Children's Clinic will participate. A late afternoon course (4.30 to 6) will take place at the London Temperance Hospital from February 8th to 19th for the convenience of general practitioners. The Queen Mary's Hospital (Stratford) has arranged a general intensive course in medicine, surgery, and the special departments daily from February 15th to 27th. Opportunity will be given for practical study in gynaecology and obstetrics. A copy of each syllabus of the foregoing courses and of the programme of the general course arranged by the Fellowship may be had from the Secretary at No. 1, Wimpole Street, W.1.

THE General Council of King Edward's Hospital Fund for London at its meeting on January 12th adopted a resolution of regret at the death of Dame Louisa Aldrich-Blake and of its high appreciation of her services as visitor, and as a member of the Council and of the Hospital Economy Committee.

A SPECIAL two weeks' course in cardiology will be held at the National Hospital for Diseases of the Heart, Westmoreland Street, W.1, from January 18th to 29th. Systematic and clinical instruction in the wards and out-patient department each day. The fee for the course, which is limited to sixteen, is £7 7s.

A POST-GRADUATE course, consisting of clinical lectures and demonstrations, teaching in the out-patient department, and lectures on the anatomy, physiology, and pathology of the nervous system, will be held at the National Hospital for the Paralyzed and Epileptic, Queen Square, W.C.1, from February 1st to March 26th.

A LECTURE on insanity, legal and medical, will be given at University College, London, by Sir Theodore Piggott (late Judge in the Allahabad High Court), on Wednesday, January 20th, at 5.30 p.m. The chair will be taken by Sir Archibald Garrod, Regius Professor of Medicine in the University of Oxford. The lecture is addressed to students of the University of London and to others interested in the subject. Admission is free without ticket.

THE annual general meeting of the Medical Officers of Schools Association will be held at 11, Chandos Street, Cavendish Square, W.1, on Friday, February 5th, at 4.15 p.m. After tea Dr. R. A. O'Brien, C.B.E., D.P.H., Director of the Wellcome Physiological Research Laboratories, will read, at 5 o'clock, a paper on the prevention of diphtheria and scarlet fever by modern methods. If possible, reactions will be shown.

THE title of the address to be given at the social evening of the Royal Society of Medicine on February 1st, by Dr. F. J. Poynton, has been changed to "The part taken by doctors in the early days of aeronautics."

At a meeting of the Royal Sanitary Institute in the Town Hall, Bradford, on Friday, February 5th, a discussion on child welfare centres and their adjuncts will be opened by Dr. J. R. Kaye, M.O.H. West Riding, at 3 p.m. The subject of town planning and improvement areas will be discussed at 5 p.m.

A MEETING of the Central Midwives Board for England and Wales was held on January 7th. A penal session was held first, followed by the ordinary monthly meeting. Business dealt with included the appointment of Dr. Jervis to represent the Board at the Congress of the Royal Sanitary Institute to be held this year. Dr. T. O. Halliwell was approved as a lecturer at Dewsbury for a period of twelve months, and approval as teachers was granted to a number of applicants. The next meeting will be held on February 4th.

THE Royal Society of Medicine announces that the William Gibson research scholarship for medical women will be awarded in June, 1926. Applications, with schedule of proposed research, two testimonials, and a statement of professional training, and appointments, should be sent to the Secretary of the society, 1, Wimpole Street, London, W.1, by June 1st.

THE International Stomatological Association has been reorganized with Dr. Chompret of Paris as president, Dr. Allaës of Antwerp as general secretary, and Dr. A. Asgís of New York as assistant general secretary.

DR. C. ACHARD has been elected general secretary of the Académie de Médecine for a further period of five years, and Professors Sabrazès of Bordeaux and Pic of Lyons have been elected corresponding members.

MR. HENRY KIMPTON announces for early publication a *Descriptive Atlas of Visceral Radiograms*, by Drs. A. P. Bertwistle and E. W. H. Shenton, and an *Introduction to Clinical Perimetry*, by Dr. H. M. Traquair.

SURGEON CAPTAIN M. H. KNAPP, R.N. (ret.), has been appointed a Knight of Grace and Dr. G. P. Meldoun an Esquire in the Order of the Hospital of St. John of Jerusalem in England.

THE Hastings Town Council has taken over the White Rock Baths on the sea front and is about to remodel them. It has, we are informed, received the collective opinion of the medical men in the district and is now making inquiries as to arrangements at other spas.

THE Committee for Public Health Education, Federated Malay States, has issued a semi-popular pamphlet, written by A. Viswalingam, assistant medical officer, on yaws, which is there called "puru." It is an example of the interest now taken in the prevention of disease in tropical countries.

SIX new cases of leprosy have been notified in Norway this year, the highest number for several years. In five cases the source of infection was known and in one the infection probably originated in Sweden. In 1922 there were no new cases, and in 1923 only two.

At the third congress of the Italian Society of the History of Medicine and Natural Sciences recently held at Venice the president, Professor D. Giordano, unveiled a bas-relief of Tommaso Rina, a Venetian surgeon who died in 1843.

FOLLOWING the examples of Brussels and Toulouse, Montpellier, Marseilles, and Bordeaux are to hold medical congresses under the name of Journées médicales in 1926, 1927, and 1928 respectively.

MEDICAL art-lovers within reach of London should not fail to visit during the next few weeks the forty-ninth winter exhibition of the Royal Academy of Arts at Burlington House, which is devoted entirely to the works of the late John S. Sargent, R.A. This wonderful loan collection of more than 600 oil-paintings, water-colours, drawings, sculpture, and architectural decorations, brings together, in almost overwhelming abundance, examples of the artist's work at every stage in his career. The versatility of Sargent's genius will impress everyone who makes a tour of the galleries. If he had never painted a full-dress portrait, his landscapes and studies alone would proclaim him master; and if he had never touched oil and canvas, the charcoal heads and pencil sketches, and above all the water-colours, would assure him a place among the great pictorial craftsmen. There are three medical portraits in the exhibition: the quiet and sympathetic oil-painting of Dr. Elizabeth Garrett Anderson, contrasting with the flamboyant society figures around her; the charcoal drawing of Sir St. Clair Thomson, dated 1913, and recognizable at a glance both as a Sargent and as the urbane President of the Royal Society of Medicine; and an interesting study in oils of Dr. William Playfair painted in 1887. War pictures include the immense mural decoration entitled "Gassed," showing parties of men blinded with mustard gas arriving at a dressing station on the Doullens-Arras road in August, 1918.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The **GRAPHIC ADDRESSES** are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westcent*, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent*, London.

MEDICAL SECRETARY, *Mediscera Westcent*, London.

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Incillux*, Office, 6, Edinburgh).

QUERIES AND ANSWERS.

A RETIRED medical officer, aged 45, with some tropical experience, asks for information regarding the method of obtaining a post as medical officer on a rubber or tea plantation in India, Ceylon, or Malay States, and as to the usual pay and term of service.

INCOME TAX.

Depreciation on Motor Car.

"W. F. W." inquires whether in claiming depreciation on a car bought in 1922 the percentage allowance should be based on the depreciated value or on the original cost.

* * The allowance is for depreciation by wear and tear during the year of assessment, and the depreciated value has been held to be the correct basis. Where this view is taken by the authorities (and it seems to have become general) it is not practicable to resist it. At the same time it is not likely to make much difference in the long run, inasmuch as the greater the depreciation allowances made the less will be the deduction due for the net renewal cost when the car is replaced.

Partnership Expenses.

"R. H. W. D." proposes to take a junior partner and to reserve the two motor cars used in the practice as his individual property. Will this affect the allowance to be claimed when a car is purchased in the joint names of the partners in replacement of either of the two present cars?

* * It certainly should not do so, as a matter of common sense, and neither should it, we think—though this is not so free from doubt—as a matter of law. If, as we gather, a new car will be purchased on the joint partnership account there seems to be no reason why the existing cars should not be included (as "R. H. W. D." suggests) in the partnership valuation and any possibility of objection to the future claim thereby extinguished.

LETTERS, NOTES, ETC.

HOSPITAL PROVISION FOR ANTE-PARTUM HAEMORRHAGE.

"G. P." writes: May I draw attention to a problem in midwifery practice still more urgent and unsatisfactory than that of puerperal fever? I refer to the lack of adequate hospital provision for cases of ante-partum haemorrhage. The Poor Law Institution may be several miles distant from the patient's own home; in any case, the difficulty and expense of sending the patient to stand by for many hours, and the difficulty of finding a hospital near the home, yet, following tradition which dates from before the days of Lister, these acute surgical emergencies—in this district and, I believe, in others—are refused by the local general hospitals.

THE NATURAL FOOD OF A BABY.

DR. J. T. MACLACHLAN (Giffnock, N.B.) writes: I was many years in practice before I realized that cow's milk is not the natural food of a baby, but the natural food of a calf. I believe that it is in the way of pain from colic, due to indigestion in the stomach or bowels, or both. I have seen milk diluted with plain water,

barley water, lime water, etc., fail to give the baby peace. I remember being called to see a baby whose sole complaint, in its mother's eyes, was it cried so much at night that the father had to pace about with it that he was not fit to go to his work in the morning. I prescribed the following mixture with complete success: Liq. pancreatic. ʒiij, sod. bicarb. ʒj, sp. chloroform. ʒj, glycerini ʒss, aquae ʒiv; a teaspoonful with each feed. It seems that the curd of cow's milk in the baby's stomach is too hard to be broken up with ease, and that the pancreatic extract solves the difficulty. I remember attending a baby who could not tolerate milk. It vomited persistently and wasted away and seemed to be dying. Horlick's malted milk, cooked with water, was prescribed for it, and it immediately stopped vomiting. On this food it was fed for six months, and, undoubtedly, Horlick's malted milk saved its life. Let me impress on young practitioners the dictum that cow's milk is not the natural food of a baby.

PRICES OF MOTOR CARS.

The *Motor* has supplemented its issue of January 5th with a little pamphlet containing the prices and condensed specifications of 1926 motor cars arranged alphabetically. With this pamphlet the prospective purchaser of a car is able to compare the prices and to study the differences in valves, horse-power, and body of the cars of nearly 150 makers. The patriotic motorist will be pleased to see that about sixty of these makes of car are of British origin, and that, on the whole, the price of British-made vehicles compares very favourably with that of similar cars made abroad. The pamphlet forms a useful little handbook.

MEDICAL INSURANCE AGENCY.

THE Medical Insurance Agency (British Medical Association House, Tavistock Square, London, W.C.1) has received three inquiries about various forms of insurance unaccompanied by the name and address of the inquirer:

1. For partnership insurance and for insurance of a Daimler car (1924), 16-h.p.; the applicant, who probably lives in London, states his age to be 62.
2. For insurance of Renault 8.3-h.p. car, 1926 model, two-seater.
3. For insurance of Morris-Cowley car, 1925 model, four-seater.

THE LATE DR. LLOYD OWEN.

DR. Y. M. JONES-HUMPHREYS (Cemmaes Road, Montgomeryshire) writes: It may be of interest to Welsh members of the British Medical Association to know that the late Dr. David Lloyd Owen of Birmingham (of whom an obituary notice appeared in the *JOURNAL* of January 2nd, p. 37) was twenty-third in descent from Einion ap Seisyllt, Lord of Ardudwy in North Wales, whose motto was "Goreu Gledwr Galoudig."

ACUTE INTESTINAL OBSTRUCTION.

DR. A. J. CAMPBELL (Edinburgh) writes: This is what another general practitioner thinks. Sir William Taylor's paper (November 28th, 1925, p. 935), and those which followed, were not pleasant reading to me. They raised some disquieting questions in my own conscience. They roused no resentment. Frequently we are disturbed by the fact that we sound advice we need to us sound advice we need years have been full of tears to anticipate complete diagnosis has been that complete diagnosis is made earlier than it used to be. The sum total of the discussion was a great advance on general practitioners. For this we owe men who conducted it. I hope my shaken out of my peace of mind by people like Sir William Taylor.

TOBACCO AMBLYOPIA.

DR. J. E. S. OLD (Nyasaland) writes, with regard to Mr. A. S. Percival's reference to tobacco amblyopia (September 19th, 1925, p. 513), to point out that tobacco contains several alkaloids. The amount of these depends on the relative proportions of nitrogen and various salts in the soil in which the tobacco has been grown. Amino-acids are formed during curing and fermentation, and the grower submits tobacco to special treatment to eliminate all objectionable compounds. Dr. Old suggests that it is possibly one of these compounds occurring in coarse low-grade tobacco which gives rise to amblyopia.

INFLAMMABLE COMBS.

DR. T. WILSON AIRD (Hove) writes: The letter of Colonel Elliot (*JOURNAL*, December 5th, 1925, p. 1089) respecting inflammable toys, hair-combs, etc., reminds me of a case to which I was called some years ago. It was that of a young girl who had been lying on the hearthrug in front of a brisk fire, reading. She was suddenly aroused owing to her celluloid hair-comb becoming violently ignited. Her sisters promptly put out the fire with cold water, but the victim sustained not only a severe shock but a serious burn on the scalp and a resulting scar about half the size of the palm of the hand, which of course remained bald.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 48, 49, 52, and 53 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at pages 22 and 24.

A British Medical Association Lecture ON POST-ENCEPHALITIC PARKINSONISM;

WITH SOME REMARKS ON THE RESULTS OF
TREATMENT BY BELLADONNA.*

BY

ARTHUR J. HALL, M.A., M.D. CANTAB., F.R.C.P.,
PROFESSOR OF MEDICINE, UNIVERSITY OF SHEFFIELD.

Of all the later manifestations of epidemic encephalitis that which is known as Parkinsonism, to distinguish it from Parkinson's disease (paralysis agitans), is not only the most common but the most serious. It has been estimated to occur in about 25 per cent. of all cases of epidemic encephalitis. Probably this is too high, and as a matter of fact there are many difficulties in making an estimate at all. Thus, the figure will vary with the time after the epidemic at which the estimate is made. It is by no means uncommon for the condition not to show itself for six, twelve, or eighteen months after the acute attack, or even, in rarer cases, not for years.

In the second place, the original number of cases of encephalitis in any single epidemic can only be estimated by the number of cases which are notified as such. As time goes on, however, it is found that a large number of Parkinsonian cases appear among patients who were not included in the original list of notified persons, the acute attack having been so slight as not to call for medical attention. If these are added to the list it is obvious that the proportion of Parkinsonian cases must become improperly raised, because it is likely that quite as many other inhabitants also had mild attacks without developing sequelae. If, on the other hand, one takes the figures of notified cases only, there is the fallacy that probably the mildest cases are omitted from the list. Out of 300 cases of encephalitis notified in the city of Sheffield during 1924 about 20 per cent. were definitely Parkinsonian at the end of 1925, so that the rough estimate given above is not very far out for notified cases; but there are almost as many Parkinsonian cases in the district traceable to the same year's outbreak who were not among the notified.

GENERAL FEATURES.

The general features of the disease are so familiar that it is not necessary to devote much time to their description. One of them is an increase of muscular tone. This leads to the postural changes which make the condition so easily recognizable at first sight. Whatever part is affected the resultant posture assumed when at rest is, with certain exceptions, the same in all cases. These postures are not the natural postures of rest, nor are they postures habitually assumed by the neuro-muscular system in ordinary life. Indeed, they cannot be said to be restful postures, using that term in the ordinary sense. To a normal person they are distinctly irksome and tiring, yet in the Parkinsonian condition their continuance appears to cause no undue fatigue. They are most noticeable in the head, upper trunk, and arms. The bowed head, which at first sight suggests muscular weakness allowing it to fall forwards, is in reality an active pull. It may continue just the same against gravity when the patient is laid on his back and the supporting pillows removed. It is sometimes more marked on one side than the other, so that the pull forwards is oblique. In one of my cases it was so marked as to cause caries of the cervical spine to be suspected.

Hypertonus and Tremor.

This hypertonic condition leading to postural changes is, of course, a familiar feature of ordinary paralysis agitans, but its importance in that disease is usually overshadowed by the accompanying tremor, which dominates the picture. In post-encephalitic Parkinsonism tremor also occurs, but its amount is, as a rule, considerably less. In a few cases it is severe, or becomes severe; in most, at any rate

for considerable periods, it is only slight; and in a certain number it is practically absent, and remains so.

It must not be forgotten that in making these statements I am speaking of cases of which nobody has yet seen the end. The oldest recognized post-encephalitic case cannot be of more than eight or nine years' duration, even if infected in the first known epidemic, whilst in this country by far the greater number of Parkinsonian cases date from the outbreak of 1924, and their duration is thus under two years.

There seems little doubt that "tremor" and "hypertonus" are distinct processes. Walshe has shown that hypertonus may be for the time completely removed in an affected muscle by the local injection of novocain, whilst tremor is not at all reduced thereby. Other drugs which also remove the hypertonus to a considerable extent and for considerable periods do not as a rule cause similar improvement in the tremor.

Sialorrhoea.

Sialorrhoea is a striking and often an early symptom. In its mildest degree there is merely a sense of increased moisture about the lips, which becomes rather inconvenient when talking or about meal times. It may often be recognized by the presence of a few bubbles between the lips when the patient is telling his history. In more marked conditions it is obviously inconvenient, and the saliva requires frequent efforts to swallow it. At times it even escapes from the angles of the mouth. In the severe stage it is a more or less continuous "drooling."

Frequency of Pulse Rate.

Another sign which appears to be common is an increase in the frequency of the pulse rate. This has been noted by various observers. My attention was called to it by Dr. Howitt of York, with whom I saw a typical case in a young woman. Her pulse was persistently 120 or over. A few days later an examination of the pulse rates of all the Parkinsonian cases attending my hospital out-patient clinic on one morning was made, and we found that the average in 13 cases was 109. The highest was 128, the lowest 96. An examination of the records of the pulse rate in five in-patients, taken over periods varying from two to twenty-six weeks, when they were lying in bed and afebrile, was 96.

Slowness of Action.

The most characteristic feature of Parkinsonism is the extreme slowness of action. It is this which gives the chief early clue to the condition in many cases. It may be limited to one part, or it may be generalized. It may be obvious to the patient even when very slight, or it may be hardly realized by him even when obvious to the onlooker. This difference appears to depend partly on the extent of its distribution. Thus it is quite common for the onset of the disease to be noticed by the patient himself, as an inability to use one hand as freely or as quickly as the other.

A musician told me that his first trouble was an inability to keep up with the right hand at the same pace as the left. A shorthand typist whose right hand was alone affected found a similar difficulty. A married woman found that in her housework her "right hand was lazy." A man with the left hand only affected said that when "dealing" he could not get the cards away with his left thumb and finger. In all these cases the patient had the opposite healthy limb for purposes of comparison.

When, however, both arms and the head and neck are affected I have seen cases in which the patient, although extremely slow, failed to appreciate that he was slower than before. Two young men whose Parkinsonism began somewhat insidiously were discharged from their posts because of their slowness. Both of them complained bitterly that so far as they knew they did things just as quickly as before.

Such slowness, when generalized, shows itself in everything, but is necessarily most noticeable in the ordinary daily actions in which the arms are principally involved—such as dressing, washing, feeding, putting on boots, etc. Whether really appreciated by the patient himself or not, this soon becomes a source of trouble in the household, and it is not long before someone has to assist him. So that

* Delivered before the Tunbridge Wells Division on December 18th, 1925.

whether they actually appreciate the slowness subjectively or not, it is daily and even hourly impressed on them from without. What, however, they do complain of is the constant overwhelming efforts that are required to perform these and all other actions of daily life.

We have recently been attempting to measure this rate of ordinary actions, and find that it presents some very interesting features. In the case of unilateral arm affections the difference in rate of movement on the two sides is very clear, whilst in the generalized cases with extremely retarded action the rate of movement may be at least ten times slower than normal.

The amount of actual muscular weakness is variable. That the muscular power does eventually fail in most cases is certain, but that it may remain fairly good for long periods is equally so. One of the most striking differences between Parkinsonism and paralysis agitans is the unexpected muscular strength which the former may at times exhibit. Possibly this may be due in part to the different ages at which the two conditions arise.

Time does not permit of more than a passing reference to many other interesting and important features. The mentality of these cases is most varied. Some are profoundly depressed and melancholic; a certain number have attempted suicide, some with success. Another group appear quite apathetic, they seem to have given up the struggle, or accepted it from the first as hopeless. There is, however, a third type, whose cheerful sanguine optimism appears to be pathological. They are always "better" in spite of the complete absence of any improvement. Nor is it possible to discuss the phenomena of micrographia, of the festinating gait and quick speech, or the curious changes in the blink reflex.

TIME OF ONSET.

Whilst in a few cases the onset is early, in the greater number it is late. Among 120 cases of Parkinsonism which have come under my personal notice the most common time of onset has been six to twelve months after the initial attack. Occasionally it has been longer, and, as is well known, cases have been recorded in which there have been intervals of five, six, or even seven years. It is, however, often difficult to fix the exact time of onset, as this is often insidious, and in many cases the beginnings are not recognized as such, hence the date of onset is too late.

Careful inquiry often shows that Parkinsonism really dates back much further than is supposed. Thus in one patient in whom it was said to have begun in the spring of 1924, I found that slowness had been noticed two years before—in June, 1922—and that he was actually discharged from his work on that account in October, 1922. As a matter of fact, it was the shaking which began in 1924 and led to the diagnosis. His initial attack of encephalitis had evidently been in March, 1921, when he was feverish, drowsy, and had "religious" delirium.

In some cases the interval between the initial attack and the onset of Parkinsonism is said to be one of complete recovery. In my experience that is rare. In most cases the recovery has been anything but complete, and in many there has been a series of changing phases—insomnia, respiratory anomalies, changes in moral character, mental abnormalities, rapid increase in weight, in some polydipsia, neuralgic pains, and so forth. With the onset of Parkinsonism some of these symptoms may persist, modifying the clinical picture, though not an essential part of it.

PARKINSONISM FOLLOWING INJURY.

In two of my cases the Parkinsonian syndrome first showed itself in recognizable form soon after an injury. This is obviously of importance in relation to the question of compensation, and deserves consideration.

The first case which I saw was that of a man aged 45. He was a farmer, and in this case no question of compensation arose. There was no history of previous illness, and no date for the encephalitis could be obtained. In December, 1924, he wounded his right hand. This was followed by an axillary abscess. After this he complained of stiffness in the back, from which he could not get relief. He said that when he turned "all of a sudden" it persisted during the first half of 1925. In July the feeling of stiffness extended to the neck and sialorrhoea was

noticed. Stiffness of the jaws when eating also occurred, so that they became fixed. I saw him in August. He was then a typical case of Parkinsonism, with tremor of the tongue and lips, sialorrhoea of the second degree, marked rigidity of the trunk, slight tremor in the right arm and leg, and "monotone" speech.

In this case the date of infection must remain unknown. It may have been at or subsequent to the date of injury to the right hand. Seeing, however, that there were no symptoms pointing to this, and that as a rule Parkinsonism is delayed until six to twelve months after infection, it seems much more likely that his primary infection was one of those which occurred, unnoticed, during the big outbreak in the first half of 1924. The second case presents no such element of uncertainty.

The patient, a man aged 51, had a definite attack of epidemic encephalitis in March, 1924, with diplopia, insomnia, and, later, lethargy, and was notified at the time. He recovered sufficiently to continue his work as a cutler—a skilled trade requiring sureness of eye and arm—until May, 1925. He then bruised the left thumb, which became septic. This was followed by swollen painful axillary glands. I saw him on September 17th, 1925. The wound had not healed; he presented typical Parkinsonian symptoms, with head bent forward, tremors of tongue, sialorrhoea, unequal pupils, loss of convergence, weakness of left face.

In this case the question of compensation did arise and it was impossible to say that the injury played no part in causing his symptoms. There are several reasons for thinking that it is more than coincidence. Paralysis agitans may follow very soon after an accident. This possibility is mentioned in the textbooks, and I have myself seen more than one such case. Again, in a somewhat similar form of nerve poisoning—namely, syphilis—the frequency of cerebral lesions appearing as the result of trauma is universally recognized.

Finally, some interesting observations have recently been made on cases of encephalitis following vaccination, which may have some bearing on this point. If trauma plays a part at all, it is probably that of unmasking a latent Parkinsonism and precipitating its onset.

PROGNOSIS.

The question of prognosis is one of considerable difficulty. A complete answer to it is still not possible because sufficient time has not yet elapsed to follow most of the cases to their termination. It is, however, now possible to say more than two years ago. Some of the cases progress very rapidly. Two of my cases from the 1924 epidemic died within six months from the onset of Parkinsonism. Others from that and from previous epidemics have died after rather longer periods. The total number of deaths, however, from Parkinsonism has not been large. In a second group the disease has progressed so that the patients have become helpless, and require constant attention. In this stage, however, they seem to remain stationary: their general health keeps good, and the disease does not seem to alter much one way or another. There is a third group in which the condition does not develop into more severe or crippling phases; indeed, it hardly seems to change at all. Weeks and months go by, and the syndrome does not extend its original limits or change its character. Indeed, in some respects they appear to be rather better, probably because with the adaptability of youth they are able to compensate for their partial disability.

One man attending my clinic, a tall powerful fellow in the thirties, had his primary infection in March, 1919. In 1920 he had marked festination and retropulsion. The face and arms, however, were less affected, and there was hardly any bending forward. Now, five years later, he has to a considerable extent overcome the festination by walking slowly and deliberately. He is very clumsy, and if he has to go through a difficult or narrow place, or if he has to hurry, the festinating gait returns at once. In ordinary circumstances, however, it has gone. After five years he has not recovered, but is not in any way worse.

Another patient, a married woman, aged 33, began also in 1919. In her case no part except the face and the right arm has ever been involved. The latter is hypertonic and slower than the left, with definite postural change. This has not increased at all in five years; in fact, she has learned to make the arm more useful, and it does not inconvenience her so much.

It is clear, then, that the condition may remain stationary for long periods. But in arriving at a prognosis in any individual case it must be remembered that, besides these stationary cases, instances do occur in which temporary improvement may take place of a surprising

character, even in patients who have been bedridden and helpless for long periods. I am not here referring to the condition known as "kinesia paradoxa," with which everyone who has seen many of these cases is familiar. Striking examples of this momentary alertness and agility of patients whose habitual slowness of action is extreme have been frequently quoted in the literature.

Among my cases a man with extreme rigidity and marked tremor, who can only shuffle along, will suddenly go off with a "hop, skip, and jump" for a few yards, as agile as a boy. Directly afterwards he returns to his Parkinsonian shackles. A youth with a similar advanced condition was one day persuaded to bathe in the sea; on coming out of the water he sprinted along the beach to his mother as well as ever he did in his life, only to relapse into his previous state when he reached her.

The periods of improvement to which I wish to call attention, although not so sudden in onset or so dramatic in character, are surprising in extent, and last, at any rate, for a considerable time.

TREATMENT.

Hyoscine.

In 1901 Erb first pointed out that hyoscine hydrobromide (scopolamine) has a definite effect in relieving the rigidity in paralysis agitans, and since then it has been frequently used for that purpose. More recently various observers have recorded its value in cases of post-encephalitic Parkinsonism. In a certain number of cases it produces quite definite and even marked improvement.

Hohman¹ has reported its effects in eighteen cases under his care; he made three groups, according to whether the improvement was slight, definite, or marked. Of the 18 cases, in 6 the results were slight, in 5 definite, and in 7 marked. As indicative of "marked improvement" he mentions "return to work after months of invalidism, and ability to attend to personal wants after being bedridden and helpless." Unfortunately there is no statement in his paper of the length of time over which these observations continued.

Personally I have tried it in a few cases, and in one or two the improvement has been quite definite. Probably my lack of success in other cases has been due to giving insufficient doses, for I have felt somewhat reluctant to prescribe considerable quantities of this powerful drug to out-patients seen only once a week, or perhaps even less often. Had I seen Hohman's encouraging paper earlier I might have been bolder, and more successful.

Belladonna.

That it is possible to obtain results from the administration of belladonna, in cases of Parkinsonism, has been known for some time, but perhaps insufficiently emphasized. I began to give it at first in order to check troublesome sialorrhoea, and for some time found it rather disappointing in this respect.

About six months ago it occurred to me that the doses were too small: 10, 20, or even 30 minims of the tincture were therefore given thrice daily. With these doses the sialorrhoea in some of the cases was considerably relieved, but much more striking than this was the improvement in the patients' general condition. They were obviously much more alert.

It was then tried systematically on a number of Parkinsonian patients, quite irrespective of whether they had sialorrhoea or no. The results were briefly as follows:

Out of 19 cases, 6 did not benefit at all; 3 stated they felt better, but there was little definite objective confirmation of this; in 10, however, there was no question about the improvement. In some of these the change was astonishing.

One, a youth aged 17, who had begun in March, 1924, with a most violent epileptiform and myoclonic onset, of long duration, developed Parkinsonism about six months later, with severe "drooling" of saliva. He had not washed, dressed, or fed himself without assistance for several months. Tincture of belladonna, 45 minims daily, was begun on September 16th, 1925. When he came to hospital a week later the salivation had stopped, and he was bright and alert. His mother said that he had begun to wash and dress himself. Now, three months later, although, of course, still a very obvious case of Parkinsonism, the salivation has not returned, and the improved condition persists.

A second youth, of about the same age, began similarly, with an extremely severe insomnia choreiform phase, and developed generalized Parkinsonism within a few months. He lost flesh rapidly, and became completely helpless. In the summer of 1925 he was in hospital, where he was bedridden, had to be fed, and could not stand up without support. After a few weeks he was discharged from hospital in the same helpless condition. He was brought to the out-patient clinic from time to time in an ambulance, and wheeled into the room. Tincture of belladonna was begun on October 14th, 1925, and the following week he walked into the clinic, having come by train and tram from his home—about eighteen miles away. Two months later he was still better. He now does everything for himself, chops the sticks, and helps his mother in household work every day.

Other records are briefly as follows:

Male, aged 29. After treatment with tincture of belladonna, 30 minims a day, began to wash and dress himself; he no longer requires helping with his meals. Two months later the improvement was maintained on the same dose.

Male, aged 30. Received 45 minims of tincture of belladonna daily. Salivation less; feels more brisk and lively; not so drowsy. Feels quicker in action.

Female, aged 15. Given 15 minims of tincture of belladonna daily. Not so tired; less saliva; now able to wash and dress herself; washes pots and helps in household.

Female, aged 25. After treatment with tincture of belladonna, 45 minims daily, showed great improvement: dresses and washes herself; walks better. Two months since treatment was begun. Later, this patient had a relapse. She was a 1920 case, and had recently been losing flesh rapidly.

In addition to these cases I may quote from two letters received from medical men with regard to advanced Parkinsonian cases under their care in whom belladonna has been tried at my suggestion.

The first case was that of a married woman, who had her primary attack of encephalitis in April, 1919. Parkinsonism was first noticed three years later. Although not actually bedridden, she was able to do very little, and was soon exhausted. She was put on tincture of belladonna about October 20th, 1925. On November 26th the doctor writes as follows: "Mrs. X has been on belladonna since you saw her. I pushed it up to 25 minims, but this was more than she could tolerate, and she is now having 20 minims thrice daily. The effect has been more than one could have possibly hoped for. . . . The other day she went a walk of about three and a half miles, and although very tired came home smiling and tremendously pleased with herself."

The second case was in a young single woman, of the 1924 outbreak. She could hardly stand by herself, and had to be assisted in washing, dressing, or feeding. The doctor writes: "M. has made a great deal of progress. She has even walked three miles. It is hard work to sound a note of warning to the very delighted parents."

It is obvious that a large part of this improvement is due to something more than the mere action of belladonna. In all these Parkinsonian cases the "functional" element is pronounced and "suggestion" is potent. But there are many facts which indicate that in most of these cases suggestion has not been the starting point of their improvement. Thus, at my clinic, nothing was said in the first instance to the out-patients about the virtues of the "new medicine" for the simple reason that these were quite unanticipated by the prescriber. Many drugs had been tried during the previous months without any benefit whatever, and a mere change of medicine was nothing new. Secondly, in the case of Mrs. X quoted above, the factor of personal suggestion, so far from acting favourably, rather did the opposite. The patient asked me at our interview some very pointed questions about her prospect of recovery, and I was obliged to answer them, which evidently depressed her considerably, and as the immediate result of my visit she was worse than ever. But the most convincing evidence that this is not primarily due to suggestion came from a quite independent and outside source. A few weeks ago I was asked by the representative of a large manufacturing concern to examine and report on one of their head managers, who had been off work ill for some months. He had been diagnosed as a case of neurasthenia until two weeks before, when he had consulted a leading neurologist in the district where he lived, who had recognized that it was post-encephalitic Parkinsonism. The representative, though not a medical man, gave a description so characteristic as to be easily recognizable. He said the patient was bent over, imitated the posture of his arms, and mentioned the shuffling gait, salivation, and extreme slowness. Next week the man was brought to see me. At first sight it seemed as though there must be some mistake. There was a well set-up, straight, active-

looking man without any postural changes at all. On examining him carefully, however, there were evident stigmata of his condition—a slightly tremulous tongue and lips, a suspicion of too fixed a gaze, and so forth, but everything was minimal. He said that this surprising change had begun within a few days of taking the medicine ordered by the neurologist; that for the first time for some months he had ceased to have the feeling of being "tied up by his muscles," that he could move them freely, and that, two days before, he had walked ten miles! The prescription contained three ingredients—chloral hydrate, tincture of hyoscyamus, and tincture of belladonna. It is possible that the good effects may have arisen from the hyoscyamus, and not from the belladonna. The doses were small, about six minims of each. My previous experience with the latter, however, makes me feel sure that, even in such doses, it is quite capable of producing the result by itself, and of the three ingredients was probably the chief agent.

In thus laying stress on the effects of belladonna it must be admitted that the bulk of the improvement is something inherent in the patient's nervous system—an auto-suggestion set going by a feeling of release from some constant oppression. In these cases the oppression is described by the patients as the effort required to perform any action. Directly even the slightest relief is felt from that a condition of "euphoria" is produced, which extends its beneficent influence over every part. This soon leads to the disappearance of that great mass of functional symptoms which often, in these cases, mask the extent of the real disorder. One is familiar with a similar course of events in many purely psychasthenic cases. Once a start can be made and a definite sense of improvement in one factor obtained, the reaction of the patient's own nervous system continues the process at compound interest—a circle not "vicious," but turned to a good purpose.

The difficulty in cases of Parkinsonism is to obtain the initial change, because here we have a very definite substratum of organic disease in which mechanical factors are involved. Belladonna, by acting in some way on some part of the neuro-muscular arc which is being over-stimulated in the Parkinsonian patients, relieves the hypertonia, allows the muscles to be used with less effort, and the higher centres do the rest.

That belladonna can act in this way is not remarkable if hyoscyne can do so. Both drugs belong to the atropine group, and have many pharmacological actions in common. Theoretically, the advantage should be with atropine, seeing that it has not the same tendency to a sedative action on the higher centres as hyoscyne. Possibly some combination of atropine and hyoscyne may be found to be more useful than either drug alone. My own experience in that direction, however, does not favour such a view. One of the cases in which belladonna failed signally found relief, both before and since, from hyoscyne.

Many points of interest arise in connexion with this action of the atropine group. How long can it be maintained? How can its effects be prolonged? Is the prognosis better in those cases which respond well than in those which do not?

There is also the question why some cases in whom the hypertonus seems equally well marked do not respond at all. It is interesting to note that in Hohman's series of cases treated by hyoscyne a certain number responded only slightly. Szyska² has recorded successful results with atropine pills, given for periods of three to six days, then a two to three day interval. Very large doses may be required and tolerated.

Before concluding, some reference must be made to cases recorded from time to time in which apparently considerable improvement follows divers forms of treatment. Thus, intrathecal injections of the patient's own serum are from time to time recorded as proving temporarily useful, also various forms of mechanical therapeutics are sometimes of benefit. It is, of course, possible that in any or all of these procedures some relaxation of the hypertonus may be brought about, as effective as when the atropine group is used. Our knowledge of the exact pathological process at

work is so slight that it would be foolish to deny such a possibility.

It is, however, rather more difficult to eliminate the factor of suggestion from without in any form of treatment which involves active intervention or daily personal influence. The very fact of a lumbar puncture being performed is in itself a powerful factor of suggestion. We are all familiar with Hutchison's "chronic abdominal woman" who recovers completely for a few weeks after each successive laparotomy!

Whilst, therefore, not for a moment denying the possibility that other methods may give as much relief as the administration of the atropine group, it seems possible that the former act more directly upon the reduced mental energy of the Parkinsonian patient, whilst in the latter the approach to the patient's higher centres is through the relief given to their neuro-muscular apparatus, and is indirect. Pharmacologically, the atropine group is said to have little or no effect on voluntary muscle. Whilst this may be true in normal conditions, it is not necessarily so when these are pathological.

There is no evidence that the actual lesion is in any way affected in its condition or progress by administering these drugs. Meanwhile, amidst all that is so dark and sombre in this disease, any measure that will give even temporary relief is worth our attention.

An Address

ON

INTESTINAL DIVERTICULA.

DELIVERED BEFORE THE MANCHESTER CLINICAL SOCIETY

BY

E. I. SPRIGGS, M.D., F.R.C.P., AND O. A. MARXER,

SENIOR PHYSICIAN,

RADIOLOGIST,

RUTHIN CASTLE (DUFF HOUSE), NORTH WALES.

(With Special Plate.)

DIVERTICULA, or accessory pouches of the intestine, have been noted occasionally by pathologists from the eighteenth century onwards. In recent years we have become familiar with the condition known as diverticulitis, which is due to inflammation extending from the multiple colic diverticula to the wall of the bowel and surrounding parts. This was described in this country by Sir Berkeley Moynihan¹ eighteen years ago, and has been exhaustively studied by Dr. Maxwell Telling.² More recently the development of accurate radiology has made it possible to recognize diverticula in the course of a routine examination of the alimentary canal. A good many records have been published, including two short papers of our own some five years ago³; but in most of these the association of diverticula with symptoms has either not been recognized or has received but little attention.

Some years ago I suggested that the term "diverticulosis" be used to embrace all phases of the disease, and particularly the existence of diverticula before gross inflammatory phenomena have involved surrounding tissues and given rise to the clinical signs of diverticulitis. Since then my colleague, Mr. Marxer, has been able to show that in the colon the outset of the disease can often be recognized before the little pouches have formed. This we call the prediverticular state. The nomenclature we adopt may, therefore, be set forth as follows:

- | | |
|-------------------------------------|-------------------|
| I. Prediverticular state (in colon) | } Diverticulosis. |
| II. Quiescent diverticulosis | |
| III. Diverticulitis | |

Each stage passes by gradations into the next; indeed, all the stages may be present in the same patient.

Our investigations have brought out three points. The first is that diverticulosis is much commoner than has been recognized hitherto. The second is that it is frequently associated with symptoms. The third point is that, contrary to the conclusions of nearly all writers on the subject, these symptoms are frequently amenable to treatment.

Diverticula may be found in each part of the alimentary canal, but are most frequent in two regions. The first is the duodenum or jejunum. These pouches are large, up to the size of a walnut, or bigger; they are often single, but there may be two, three, or, rarely, even more. The second region is the colon, from which small pouches arise up to the size of a pea, seldom as large as a blackberry; these are usually multiple and sometimes very numerous.

A review of the literature with references and details of our cases, which time does not permit us to deal with now, is in course of publication.*

DUODENAL DIVERTICULA.

Fig. 1 shows the radiological appearance of a typical pouch of the duodenum, a mushroom-shaped shadow being seen to lie on the inner side of the second part of the duodenum; it is connected with the gut by a fairly wide mouth, which is often indicated by streaks of barium lying in the folds of the mucous lining. These streaks are more obvious in Figs. 2 and 3.

Duodenal diverticula have been detected 38 times in the last 1,000 consecutive radiological examinations of the alimentary canal. The sexes were about equal—20 women and 18 men. In 32 of these patients only one pouch was seen. In 6 there were two or more, one patient showing half a dozen duodenal diverticula as well as several in the jejunum. In all there were 51 duodenal pouches, of which 30 were in the second part, 16 in the third, 4 in the fourth, and one in the first part.

The incidence in this series was rather larger than the above figures show; for we have learned recently that certain tiny shadows which had been thought to be due to a little barium having entered the ampulla of Vater were really incipient diverticula, as shown by re-examination of the patients after some years.

If a careful routine examination of the duodenum is made, with proper manipulations of the tube so as to get the different aspects of this part of the bowel into profile, no other special technique is needed. Details of the method will be found in the above-mentioned paper.⁴ In all cases the buttermilk meal was used.

It was assumed that these pouches, detected formerly at autopsy, were congenital in origin, and no doubt congenital pouches may, and do, occur. But the facts that they are nearly always found in later life (only two of these patients were under 40 years of age), and that we have seen the shadows grow in the course of years from a small dot to the size of a walnut or more, make it clear that, whether or no there be a congenital predisposition, the actual pouches arise in adult life. In Fig. 3 such a minute pocket can be seen lying close to a well developed diverticulum. A year later the small one had doubled its size. In the large bowel there is evidence, of which I shall speak shortly, that a local inflammation precedes the formation of diverticula. In the duodenum also it is possible that a local catarrh, by weakening the wall, predisposes to extrusion.

As a rule duodenal diverticula are not associated with duodenal ulceration, but are pushed out at weak parts of the wall, which are uncovered by peritoneum, and particularly in the region pierced by the common duct. In these patients there was only one pouch from the outer aspect of the duodenum (Fig. 4).

The largest diverticulum we have seen is shown in Fig. 5. Its vertical measurement was 4 inches. It arose from the second part of the duodenum. This photograph (left oblique) was taken one and a half hours after the opaque meal. The stomach was empty at five hours, but the pouch had not evacuated all its barium in three days, when the rest of the alimentary canal was clear. A large pocket arising from the third part of the duodenum is shown in Fig. 6.

Pouches of the jejunum can be seen in Figs. 3 and 7. They were observed in 7 patients in this series, in 4 of whom there were also pouches of the duodenum. In a recent case in which a solitary pocket of the jejunum was observed the abdomen was opened, for other reasons, and the pouch examined. It showed no pathological feature.

In the ileum diverticula (excluding Meckel's) were observed in 7 patients (0.7 per cent.); they were small (see Fig. 8), and more like those found in the large intestine, of which I shall speak in a few minutes. The appendix showed little pouches in 6 cases, one of which is illustrated in Fig. 9.

Symptoms.

Duodenal diverticula may give rise to no symptoms, and in such cases are found, if at all, during a routine radiological examination, made for some complaint of a different nature. In about half our cases, however—namely, in 18 (47 per cent.)—symptoms were present which, after careful clinical, radiological, chemical, and bacteriological examinations, were not otherwise explained, and were attributed to irritation from the pouch. Indeed, it is obvious that a blind alley, often slow in emptying, in which the contents of the alimentary canal can accumulate and decompose, will, on occasion, be a source of inflammation and discomfort. Further, the distension of a pouch by food, especially during contraction of the duodenum, or the pressure on surrounding structures, would be expected to cause disturbance.

The typical symptom is a heavy, tired, or distended feeling about the epigastrium coming on after food. The earliest interval given was half an hour and the longest three hours. In 6 patients the discomfort amounted to pain or aching, and in others nausea (6 cases), vomiting (3 cases), or diarrhoea (3 cases) was complained of. It appeared clear that in two cases symptoms of colitis were set up by the discharge of putrefactive matter from such a pouch.* In 2 cases blood was vomited. Headache, jaundice, and pain in the back were noted in one case each. In 5 of these patients the diverticulum was tender when gently pressed upon on the x-ray table; in one of them there was pancreatitis.

The symptoms are therefore various, as would be expected. They are usually, however, referred to the affected area. They sometimes suggest vaguely duodenal ulcer, but the time relations are less definite and relief with food is unusual; it was present in one only of this series.

Diagnosis.

The diagnosis is made by x rays. An exploration is much less certain, as these pouches are commonly not detected at an operation since they are extraperitoneal.

Treatment.

Treatment may be medical or surgical. In 13 out of the 18 patients whose complaints were due to irritation from duodenal pouches the symptoms were relieved entirely by a few weeks of medical treatment. The measures adopted were devised to aid the pouch to empty, to prevent or lessen putrefaction of its contents, and to promote the health of the rest of the alimentary canal.

It is often possible to observe on the x-ray table that a pouch will empty more quickly in a certain position. To this end it is necessary to define the relation of the mouth to the pouch itself and to the bowel from which it arises. For example, in the case shown in Fig. 5 the evacuation was helped if the patient lay on the right side. She was therefore directed to assume that position for half an hour at a time when most of the food would be leaving the duodenum—that is, about three hours after a meal, or, in practice, just before the next meal.

For lubrication of the pouch, liquid paraffin is given night and morning, and the patient is advised to take it always, in a minimum dose of a teaspoonful, and more if the bowels are not loose. Kerol is given two hours after a meal. The diverticulum lies so near the stomach that it is reasonable to expect the antiseptic to be effective. The kerol is omitted for about three days a fortnight to avoid any possible poisoning. Cream of magnesia or a carminative medicine often relieves discomfort or distension after food. If the gastric juice is deficient an acid drink is given after the chief meals. Food should be plain and well chewed; condiments and excess of meat should be avoided.

* In another patient in this series, who has since returned for treatment, intermittent epigastric pain, from duodenal pouches (Fig. 3), which goes through to the back, is followed for a few days by mucous colitis.

* This paper has since appeared (see Reference 4).

We have not found it possible to empty a diverticulum by manipulation; and if there is any tenderness or irritation it is better not to massage above the navel. The following are detailed examples of cases.

No. 2855.—Woman, aged 66. Eight months' history of discomfort in the epigastrium about an hour after food. Nausea in the night, vomiting bile in the morning; flatulence. The fractional test meal gave a normal gastric juice, but slow emptying, as of duodenal irritation. There was a diverticulum of the second part of the duodenum, which was tender (Fig. 2). No other lesion was found in the alimentary canal or elsewhere. The symptoms disappeared with treatment.

No. 2433.—Woman, aged 75. Thirty years' history of indigestion. The patient had been operated upon three years before for strangulation of bowel. Pain was present in the upper abdomen on waking; it was eased by food. There was also a tearing pain two to three hours after food, leaving a sore feeling in the epigastrium; also pain in the left flank, worse after motoring, and achylia. A very large double pouch (see Fig. 5), which retained material seventy-two hours, was connected with the second part of the duodenum. There were multiple small diverticula of the splenic flexure which were probably the cause of the pain in the left flank. Operation was not advised on account of great improvement with treatment, and of age.

No. 1424.—A man, aged 54, gave at least seventeen years' history of attacks of nausea and vomiting, discomfort in the lower abdomen three-quarters of an hour after food, and diarrhoea. Haematemesis three times. There was a double pouch, or two pouches, of the second part of the duodenum. Subacid gastric juice. There was no x-ray or faecal evidence of colitis. He recovered with treatment. Two and a half years later he wrote that he had kept well.

Surgical treatment was employed in one of these patients on whom an operation was performed for the diverticula.

No. 1571.—A man, aged 54, complained of nausea, with occasional vomiting, and attacks of diarrhoea. He had brought up blood three times in twenty-three years. Six or seven diverticula of the duodenum and three of the jejunum could be made out. X-ray photographs showed a maze of air spaces and levels of fluid secretion and of opaque food. The gastric juice contained no free hydrochloric acid, and suitable treatment for achylia, especially the administration of acid, gave much relief for a time. Vomiting recurred, however, and in 1921 gastro-enterostomy was performed. At the operation all but the postero-internal diverticula were traced. Three were seen in the second part of the duodenum, three or four in the third part, and three in the proximal jejunum. The largest pouch occupied the head of the pancreas; it showed a cicatrix at its mouth. Those in the proximal jejunum showed no evidence of former inflammation. After operation some nausea was complained of for a year, but now, four years later, it is rare. He has no other symptoms and follows an active life of work and recreation.

In cases which do not respond to medical treatment it appears that excision of the pouch would be beneficial and justifiable. It might not be possible in the case of diverticula which are embedded in the pancreas, and in these gastro-enterostomy might be done with advantage. Sir Harold Stiles, in a letter of May 24th, 1922, described the removal of a diverticulum 2½ inches long from the duodenum. "It was the size of a hen's egg, and the fundus of it presented between the stomach and the colon, covered by the upper layer of the transverse mesocolon. The neck, which admitted the forefinger, sprung from the region of the opening of the pancreatic duct, and the wall of the diverticulum contained small areas of pancreatic tissue. The muscular coat ended abruptly at the neck."

The pouches may be missed, as I have mentioned, by competent surgeons, to the detriment of the patient, even when their situation is known. We suggest that the mouth, which is seldom narrow, should be palpable, and that the opposite wall might be intussuscepted into it by the finger. It would be necessary to go behind the peritoneum to find the usual form of duodenal pouch. Mr. D. P. D. Wilkie, in a letter, states that from his experience there should be no difficulty in exposing the pouches by dissection.

Operation would have been recommended in at least two other of these patients had it not been that there were contraindications, including age, that the patients were no longer active, and that medical measures gave a reasonable degree of relief.

DIVERTICULA OF THE COLON.

The first point I wish to make about diverticulosis of the colon is that it is common. It was found in no fewer than 100 cases in this series of 1,000 radiological examinations of the bowel, of which 71 were men and 29 women. Like duodenal diverticulosis, it occurs in the latter part of life.

The average age was 58 years, whereas the average age of the 1,000 patients was 45 years. It is unlike the duodenal form in that the pouches are small and multiple, and that no one has seriously believed that they can be congenital in origin.

Diagnosis.

The diagnosis is made by x rays. The pouches may be detected with a barium enema, as shown in Fig. 10. They may be well shown with a barium meal, especially in those parts of the bowel in which the lumen is empty and the pouches remain filled, as in the descending colon in Fig. 11. They show up best, however, after the whole of the barium has left the lumen, as in Fig. 12. If the pouches are fairly large with wide necks the material in them empties readily; in those with narrow necks it breaks up and passes out in small fragments; a trail of such is shown in this figure in the left-hand part of the transverse colon at the top of the plate. If the neck of the pocket is exceedingly narrow it may, however, retain its material to form a stercolith. Faint shadows of stercoliths can be recognized along the descending colon in this photograph, and were obvious in the negative.

Diverticulosis is most frequent in the pelvic colon, though the descending part is also a common site. It may occur in all parts of the large intestine. We have also observed multiple diverticula of a similar nature, as I have already mentioned, in the terminal ileum. Fig. 13 shows graphically the distribution in the large bowel in these cases. The

FIG. 13.

sex incidence is also shown, the upper striped part of each column representing the females.

The *prediverticular state*, the first stage of diverticulosis, was discovered by Mr. Marxer, and described briefly about two years ago.³ Part of the wall of the bowel, instead of showing its natural free curve of outline, appears fixed and contracted, with a profile of minute irregularities. This may only be seen on one side of the bowel, but if it involves the circumference there is the appearance of a stricture, as in the left-hand photograph of Fig. 14. In Fig. 15 several inches of bowel are involved. At the upper part formed diverticula are present, and further up there is the typical appearance of the second stage of diverticulosis, with pouches, and a normal or nearly normal segmentation of the bowel. When the *prediverticular state* involves the whole circumference the large bowel shows an appearance not unlike the normal outline of small gut. This is illustrated in Fig. 16. The *prediverticular appearance* is not the result of irritation from small herniae, as it precedes their formation. This appearance was detected in 20 out of the 100 cases in this series. If, however, we add cases investigated since, we have now recognized it in 37 cases. The areas affected are usually small and limited; but patches may be seen all about the colon, and in one case the whole of the descending colon and sigmoid were involved. It is while this stage is in progress that the minute herniae begin to be pushed through. Small diverticula can frequently be recognized in or near to the affected areas. In our experience the buttermilk meal is the best for showing the *prediverticular state*, or, indeed, for any other fine detail in the alimentary canal.

The second stage, of formed diverticula, may be associated with some irregular segmentation, but frequently is not. The small pouches are seen upon an otherwise normal bowel, as in Fig. 10. If the necks are narrow, material is retained within them and the barium extends partly round this residue, but does not displace it, giving a crescentic appearance, such as is seen in some of the pockets in

FIG. 1.—No. 612; male, aged 51. One hour after opaque meal; supine, right oblique. A diverticulum from the second part of the duodenum. Agastrojejunostomy is seen on the right.

FIG. 2.—No. 2855; female, aged 66. Half an hour after meal; prone. A diverticulum from the second part of the duodenum. Note the plication of its mouth.

FIG. 7.—No. 2112; female, aged 69. One and a half hours; left oblique. A pouch beyond the duodeno-jejunal flexure, and a large one further on; there is also a typical extrapancreatic duodenal pouch, seen in its narrow profile, showing a concave outline where it lies against the pancreas.

FIG. 4.—No. 2446; female, aged 69. Five hours; supine. A large pouch arising from the free outer border about 5 inches from the pylorus. It appears to be segmented in the middle. There is also a deformity of the fourth part of the duodenum.

FIG. 3.—No. 2249; female, aged 48. Half an hour; supine, left oblique. A minute pocket can be seen close to a developed pouch. The small one was observed to have doubled its size a year later. Two jejunal diverticula are present.

FIG. 5.—No. 2433; female, aged 75. One and a half hours; supine, left oblique. A large pouch arising from the second part of the duodenum and pushing the duodenum forward.

FIG. 8.—No. 2635; female, aged 61. Eight and a half hours; supine. Small diverticula are seen along the inner border of the terminal ileum; these are comparable in appearance to the multiple colic diverticula.

FIG. 6.—No. 3022; female, aged 50. One and a half hours; prone. A good-sized pouch, with plicated neck, arising from the third part of the duodenum.

FIG. 9.—No. 1992; male, aged 48. Thirteen hours; supine, right oblique. A typical retro-external caecal appendix; a small diverticulum projects downwards from the highest point.

FIG. 10.—No. 2959; female, aged 44. A colon filled with a barium enema. Diverticula are seen protruding from the normal haustra.

FIG. 11.—No. 2589; male, aged 69. Seventy-two hours after the barium meal; prone. Large diverticula of the descending colon. Others are seen throughout the bowel. A kidney stone and the appendix can also be seen.

FIG. 12.—No. 1847; male, aged 69. Two hundred hours; prone. Residues in numerous diverticula; some typical crescentic shadows. Note the speckled trail, in the distal transverse colon, of fragments discharged from diverticula.

FIG. 14.—No. 2269; male, aged 61. Barium enema. The normal segmentation of the large bowel is replaced in the left-hand photograph by a rigid appearance of the wall with small irregularities. This is characteristic of the prediverticular state; in this case it involves the whole circumference of the gut for a couple of centimetres, causing an apparent constriction. The right-hand photograph shows the same piece of bowel after three months' treatment.

FIG. 15.—No. 2620; male, aged 55. Barium enema. The outline of a prediverticular area is compared with that of normal small intestine.

FIG. 15.—No. 1638; male, aged 35. Barium enema. Shows the prediverticular state involving the whole circumference of a long stretch of bowel; formed diverticula are seen in the upper part.

FIG. 17.—No. 1163; male, aged 63. Barium enema. Shows the rigid, thickened appearance of diverticulitis, with inflammatory thickening of the bowel wall. The hausta near by showed overactivity.

FIG. 19.—Diverticulitis. Twenty-four hours after barium meal. A constriction of the sigmoid is seen, and the bowel at this region was adherent to the bladder. Further up are diverticula of the iliac colon.

Fig. 12, especially in the ascending colon. When the necks are not so narrow the intestinal contents pass freely in and out, and pouches photographed when full show their natural globular shape.

The third stage, of *diverticulitis*, has been recognized for several years and has been well described. It is due to inflammation of a pouch or pouches which involves the wall of the bowel in the first instance. Surrounding tissues are implicated later, causing a soft tender tumour, usually in the left iliac fossa, which may lead to obstruction, and frequently is thought at first to be malignant. The x-ray appearance is characteristic. Instead of rounded pouches are seen palisade or spike-like processes (Fig. 17) set at various angles to the lumen. They are the remains of the pouches squeezed to this shape by the oedematous and inflamed bowel wall around them. They are rigid, whereas the neighbouring haustra not involved in the inflammatory process are overactive, frequently changing their shape.

Inflammation may, of course, occur in or around a single diverticulum, and diverticulitis, in the strict sense, may arise at any time after the little pockets have become established; but the developed surgical diverticulitis I have just described is a late phenomenon, and most cases of diverticulosis never reach that stage. For example, in this series there were 5 cases only—that is, 5 per cent. Obstruction, for which colostomy was done, supervened in two of these.

Etiology.

The discovery of the prediverticular state alters the previous conception of the nature of diverticulosis. The pockets were thought formerly to be mere passive extrusions of mucous membrane through weak places in the bowel, particularly where the blood vessels pierce the wall, pushed through by internal pressure. But these observations suggest that some antecedent process takes place in the parts which are to be affected, weakening or thinning definite areas and making them liable to herniation. There is apparently a local irritation or inflammation in the first instance, the nature of which is not at present known. A bacterial cause is naturally suspected, as the mucous lining of the bowel is bathed continually with material which swarms with a variety of micro-organisms. Our colleagues, Dr. Patterson and Mr. Jeffery, have found that haemolytic streptococci are much more frequent in the faeces of patients showing the prediverticular state than in those of others; but these organisms may be found in as many as 30 per cent. of non-diverticular patients, so that the investigation must be extended to a much larger series of cases before conclusions can be drawn. It may be noted that the commonest site of diverticulosis—namely, the sigmoid flexure—is one that is especially exposed to toxic or bacterial damage from faeces; for after defaecation there is often some semi-fluid material from the transverse colon left lying here which inspissates gradually until the next movement—one, two, or more days later.

There is further evidence of a different nature to suggest that diverticulosis may be due to, or associated with, a chronic infective process. Mr. Marxer noted that spondylitis, with liability to lumbago and fibrositis, was often found in the patients with multiple diverticula. Arthritic changes are, of course, often observed, if looked for, in the spines of elderly people; and we therefore made a comparison of the films of the vertebral column obtained in the routine screening of 100 non-diverticular patients of the same average age (58 years) as the diverticular patients in this series. In the former arthritic changes could be observed in 20 per cent.; in the latter in 72 per cent. In 1,000 consecutive cases arthritic changes were seen in 19 per cent. Further, apical granulomata of the teeth, which were present in 38 per cent. of the non-diverticular control patients, were found in 65 per cent. of the diverticular. These relationships are shown in Fig. 18. In many other cases some established infective or septic condition was present, such as appendicitis, gall stones, or arthritis. Fig. 15, for example, which shows a large area of the prediverticular state, was taken from a young man with a progressive subacute arthritis.

It is obvious that the association of diverticulosis in its late stages with infective states may be, and no doubt

frequently is, in the reverse sense to that suggested; that is to say, that septio absorption from purulent material in infected diverticula may give rise to, or favours, sepsis in various parts of the body.

Constipation has been regarded as an important cause of diverticulosis. It was present, and proved radiologically, in half of these patients, but was not more frequent than in the non-diverticular. Most were taking purgatives, and would periodically be irritating the bowel wall therewith and producing stools which were more fluid than normal. We do not know whether the constipation or the aperients are the more harmful, on the average, to the vitality of the bowel wall. No association could be traced with colitis.

Symptoms.

No symptoms could be certainly recognized as pertaining to the prediverticular state, but in some instances the area involved was tender to palpation on the x-ray table.

In the second stage, of established diverticula, in about one-third of the cases there were no symptoms and no x-ray evidence of irritation of the bowel. The earlier irritation of the bowel seems to have subsided and the condition may be quiescent for long periods. In many others there were symptoms which were unexplained by any other pathological state which might be present and must therefore be ascribed to the diverticulosis. Out of the

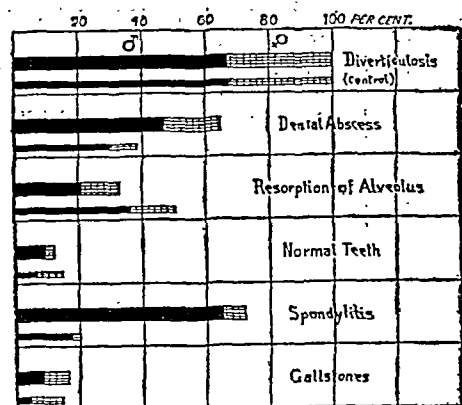

FIG. 18.—Comparison with 100 patients of same average sex and age (58) but without diverticulosis.

whole 100 cases, flatulence and abdominal pain or discomfort were frequent in nearly a half. Other symptoms, in more advanced cases, were pain or discomfort before or after defaecation, diarrhoea, alternating constipation and diarrhoea, and irregular micturition.

The following two cases may be quoted—one in the first stage and one with established diverticula:

A man, aged 51, who had frequently had influenza, complained of repeated lumbago, headaches, passage of much flatus by the bowel, and constipation. The teeth were defective; x rays showed abscesses at the apices of some of them, also exostoses in the region of the fifth lumbar vertebra, and a prediverticular state of the descending and pelvic colon. The affected teeth were extracted and the bowel and general health treated, with complete relief.

A man, aged 57, had noticed for four years a sense of incomplete evacuation of the rectum. His abdomen had been opened twice in that time, and the appendix removed, but no adequate reason for his discomfort was found. The sigmoid had been stitched to the anterior abdominal wall. On admission he complained of constant discomfort in the left iliac fossa, a sense of incomplete evacuation, and frequent micturition after an action of the bowels. X-ray examination showed diverticulosis of the descending colon and the sigmoid with mild diverticulitis. With treatment the general health improved steadily and the symptoms diminished. On readmission eighteen months later for another condition, no complaint was made of the abdominal symptoms, which had gradually disappeared.

whole 100 cases, flatulence and abdominal pain or discomfort are pain, intermittent and subacute; usually in the left iliac fossa, and a tender tumour. There may be obstruction, but it is surprising how long an inflamed, thickened, oedematous bowel may continue to be patent, with reasonable care. Adhesion to the bladder is frequent

and a vesical fistula may form. Fig. 19 shows a constriction which was adherent to the bladder. Perforation into the peritoneal cavity is rare, but may occur.

Carcinoma may arise in a diverticulous bowel, but is not frequent. There were 5 cases in our series, a smaller number than was found in 100 control patients of the same age.

Treatment.

Nearly all writers hitherto have been pessimistic about the treatment of a diverticulous bowel, some going so far as to suggest that nothing but excision of the affected bowel, which is often dangerous and not always possible, is likely to help. I can assert confidently that a practical trial of systematic treatment leads to an opposite conclusion. Nearly all cases of diverticulosis of the large bowel can be kept in health by simple medical measures; and the very few who are not can be relieved by surgery.

Paraffin is given morning and evening to permeate the faeces, grease the pockets, and help them to empty easily, without the irritation of purgatives. Even if the bowels are open naturally the oil is not omitted though the dose may be reduced to a teaspoonful twice a day. The risk of putrefaction and inflammation would be eliminated if faecal matter could be prevented from lying and putrefying in the diverticula.

It is doubtful how far antiseptics given by the mouth can affect the contents of the large bowel. In some cases I have thought that benefit has followed the use of kerol, dimol, or similar drugs. We usually douche the bowel with saline on alternate days for a few weeks with the same object. Such douches must be given at a low pressure, not more than 18 inches, the patient lying first on the left and then on the right side, and taking half a dozen deep breaths in each position. With this procedure the whole of the large bowel can be filled, as is shown daily in the x-ray room with the barium enema. The use of the so-called high or long tube, which I still find practised, is futile. It nearly always curls up, and if it did not might be harmful. It is only necessary to let the fluid run into the rectum. More than two pints should never be used. Fig. 14 shows the improvement in the prediverticular state which followed a course of douching. The constriction seen on the left is no longer obvious in the right-hand figure.

The action of the bowels is aided by the use of an anti-constipation lacto-vegetarian diet, modified to suit the individual. The following is an example:

- 7 a.m.—1/2 oz. of paraffin in 2 oz. of warm milk.
- 8 a.m.—Coffee and milk; one tablespoonful of milk sugar; wholemeal bread, butter, honey, or marmalade.
- 10.30 a.m.—A glass of buttermilk; wholemeal bread and butter.
- 1 p.m.—Fish (cooked any way); butter sauce; salad and dressing; compote of fruit; cream; toast and butter.
- 4 p.m.—Coffee, with milk or cream; marmalade; wholemeal bread (toasted if desired) and butter.
- 7.30 p.m.—Vegetable soup; some egg dish (poached, scrambled, or omelette) with vegetables or fruit—for instance, jam or jelly omelette or omelette aux fines herbes; cream cheese; wholemeal bread; butter.

The patient is told not to strain at stool, but to take plenty of time, making a short effort every third breath.

The general treatment consists, in the first place, of removal, so far as possible, of all septic states, such as diseased teeth or tonsils, or an inflamed gall bladder or appendix, provided that the state of the patient justifies the appropriate operation. A regular life with prescribed rests and exercise is of great assistance in improving the tone of the body generally and with it that of the alimentary tube. Flatulent indigestion and lack of appetite are treated by carminatives or tonics and such other measures as are indicated.

A diverticulous area should never be massaged. In a recent case in which the disease had doubtless from the appearances been present for years, severe symptoms were aroused by a course of massage which had been given about three months before the patient sought admission.

The results of medical treatment in this series were that, out of 53 patients who complained of symptoms, complete relief was obtained after a few weeks' treatment in 36. In 5 others the only symptom left was occasional flatulence, and in others there was improvement. There was no mortality.

Surgical treatment is needed if perforation of a pocket into the general peritoneal cavity takes place. This is rare, and there was no case in the series. It may also be called for if a fistula forms between the bowel and the bladder or other viscus. The most frequent need of operation is for obstruction. I have mentioned that a colostomy proved necessary in two of these cases. I should, however, not be in a hurry to operate unless there were unmistakable clinical or radiological evidence of dilatation of the bowel above the affected area or unless the condition of the patient were becoming serious; for an area of diverticulitis is capable of a remarkable degree of recovery with douching from below and paraffin from above, with perhaps a simple purgative, such as salts, as a preliminary measure; and, once recovered, it will continue patent for an indefinite period, if kept clean. The advantage of avoiding a colostomy is obvious.

The excision of an obstructed area of bowel affected with diverticulitis is frequently not possible because of adhesion or because the affection is not localized enough. I have, however, recently seen Mr. Lockhart-Mummery remove with success such a diverticulitic tumour from the sigmoid, doing an end-to-end resection.

SUMMARY.

Diverticula of the duodenum are not uncommon. They are usually single, or few, can be seen to arise in adult life, and to increase in size over the course of years. They frequently cause symptoms, which can usually be relieved by medical treatment. Intractable cases can be treated surgically.

Multiple diverticulosis of the colon is frequent. The formation of the small herniae is preceded by irritation or inflammation of the area of the bowel involved—the prediverticular state. Diverticulosis is frequently associated with various infective states elsewhere, and particularly with arthritic changes in the spine and apical tooth abscesses. It is suggested that it may be infective in origin. In late stages it is a source of sepsis.

The diverticula when formed may give rise to no disturbance for long periods. In half of the cases, however, there were symptoms referable to the diverticula. These symptoms were amenable to medical treatment in nearly all cases. The terminal stage of surgical diverticulitis was present in 5 only out of 100 cases.

THE HAEMOCHROMOGEN CRYSTAL TEST FOR BLOOD.

BY

DOUGLAS J. A. KERR, M.B., M.R.C.P., D.P.H.,

AND

VICTOR H. MASON, M.C., M.B., CH.B.

(From the Forensic Medicine Department, Edinburgh University.)

SINCE Teichmann in 1853 succeeded in producing haemin crystals, this chemical blood test has been generally regarded as a valuable and conclusive proof of the presence of blood in a stain. The procedure is simple, but unfortunately the test is not always successful, either owing to overheating, to the acid not being pure, to the inhibitory influence of rust, fat, etc., or to some change in the blood.

Numerous modifications of Teichmann's process have been advocated, but while some are an improvement the fact remains that even in experienced hands the test frequently gives negative results in the undoubted presence of blood. The uncertainty of the successful production of haemin crystals led to attempts to utilize other crystal tests for medico-legal purposes.

In 1889 Hoppe-Seyler was able to crystallize haemochromogen, and later Donagány, and also Bürker in 1909,¹

drew attention to the ease with which haemochromogen crystals could be produced by means of pyridine, and Dominici advocated the production of haemochromogen crystals as a test for blood in medico-legal cases.

Within recent years great attention has been directed to this test, especially in Germany, but, so far as we are aware, it has not found a place in English textbooks, nor is it described in English literature. We found it to offer many advantages over the haemin crystal test in the medico-legal examination of blood stains, inasmuch as the procedure is very simple and positive results are obtained in cases in which the haemin crystal test fails. It is not liable to be interfered with by overheating or by the other factors which tend to inhibit the formation of haemin crystals. It has the further advantage that the specimen after treatment affords spectroscopic corroboration of the presence of haemochromogen and therefore of the presence of blood.

The earlier observers experienced difficulties in obtaining haemochromogen crystals similar to those found in the haemin test, and Otto Leers² stated that he was unable to obtain haemochromogen crystals from stains on linen and leather. Since then, however, Takayama³ in 1912, working in Japan, has described two solutions which give eminently satisfactory results, Solution 2 being an improved form of Solution 1.

The Takayama Solution 2 consists of: Sodium hydroxide (10 per cent.) 3 c.cm., pyridine 3 c.cm., saturated solution of grape sugar 3 c.cm., aq. dest. 7 c.cm. The sodium hydroxide acts as an alkali and solvent of blood and the grape sugar as a reducing agent. All solutions now recommended for the production of these crystals contain pyridine, and according to Halliburton⁴ they appear to be a pyridine compound of haemochromogen and give the same spectroscopic tests. This would seem to explain the difficulties encountered by previous observers who did not use pyridine, and who sought to obtain crystals of haemochromogen itself. The solution keeps for one to two months, after which time it deteriorates. On the addition of two or three drops of Takayama's solution to a small piece of the suspected material on a slide, in the cold, and covering with a cover-glass, salmon-pink crystals appear within one to six minutes, giving a very characteristic appearance (see upper part of figure) under the low power of the microscope. At the same time the colour changes through green-brown, dark red, to pink, indicating the formation of haemochromogen, and thus affording confirmation of the test. If only a minute portion of blood is available this is apt to vanish during any process of heating, and thus a method which can be carried out in the cold possesses a distinct advantage.

While crystals usually appear within one to six minutes, occasionally they take longer to form when the test is performed in the cold and with freshly prepared reagent, and therefore, in these circumstances, a negative result should not be recorded until after half an hour has elapsed. We found that when using freshly prepared Takayama solution in the cold crystals did not appear for thirty minutes, and on testing with this solution at hourly intervals the time taken for the formation of crystals was found to become progressively shorter—namely, after six hours, ten minutes; after twenty-four hours, six minutes; after forty-eight hours, four minutes. On the other hand, even with freshly prepared Takayama solution, if the slide be heated until bubbles just appear, crystals

are formed almost at once, and, unlike the haemin test, there is no danger of overheating. The crystals themselves are single shallow rhomboids of a salmon-pink colour, which, when lying on their sides give the appearance of single dark lines, while the various appearances seen under the microscope are due to two or more crystals adhering to one another, giving the appearance of sheaves, fir trees, and other forms, the individual crystals of which may be made out under the high power. They are often so large that the spectrum of haemochromogen can be obtained from a single crystal, and if mounted in Canada balsam or suitably ringed round with some preparation such as gold size so as to exclude access of air, the crystals may be preserved for weeks or months; but even under the best conditions they tend to disappear. We have, however, specimens which we have kept for six months.

Mahler in 1923⁵ conducted a series of experiments contrasting the haemin and haemochromogen tests, and the results of our own investigations in the main agree with his conclusions. Before comparing the two tests we first determined which, in our opinion, was the best procedure to adopt in each case, and among others the following methods and modifications of Teichmann's test were tried for the production of haemin crystals—namely, Teichmann,

Willcox, Sutherland, Nippe, Wachholz, Wachholz - Nippe. Among these methods we had no hesitation in coming to the conclusion that Sutherland's gave by far the most consistent and satisfactory results. Sutherland⁶ describes his method as follows. On a clean slide is placed a drop of salt solution (ordinary 0.75 per cent. solution), and this is evaporated by heating over the Bunsen flame. On the white spot left by the drop are placed scraped fragments of the stained material, and to the preparation is then conveyed a drop of glacial acetic acid by means of a glass rod. The preparation is then covered with a cover-glass, after which it is gently heated till bubbles appear, when it is put aside for a time, being slightly tilted so that the liquid may collect at one part. It is then examined under a magnifying power of 200 to

Haemochromogen crystals. ($\times 75$ and $\times 250$.) The two lower sections show crystals in simpler and in more complicated formations respectively.

300. As regards the production of haemochromogen crystals, we agree with Mahler that by far the best procedure is to use Takayama Solution 2 as described above.

The following articles were selected for a comparison of the two tests: fresh blood clot; fresh stain on linen; fresh stain washed in hot water; fresh stain washed in cold water; two years old stain on linen; stains on linen and blood on a slide heated to 100° C. for half an hour and one hour; stains on linen and on a slide heated to 150° C. for half an hour and one hour; stain (one week old) on rusty tin and on wood; stain (two years old) on brown paper; stains twenty-five and forty years old on razors; stain forty-five years old on rusty razor; decomposing blood four months old; carbon-monoxide blood; and menstrual blood.

In all the above cases haemin crystals were obtained except in those of the blood stains heated to 150° C. and those which had been washed in hot water. In some cases there was no difficulty, in others it required much care, time, and manipulation.

The haemochromogen crystals were obtained in all cases without any trouble in the cold, and at once if heated; moreover, they were easily obtained in the cases of those stains heated to 150° C., those which had been washed in hot water, and those contaminated with rust; in the latter case they were easily picked out owing to their characteristic colour. In no instance where blood has been proved

to be present by other means have we failed to obtain haemochromogen crystals.

Conclusions.

A. In the majority of cases, especially with fresh stains and if care be exercised, there is no difficulty in obtaining haemin crystals.

B. The haemochromogen crystal test, however, possesses the following advantages:

1. Simplicity of technique; being obtained in the cold by simply adding the solution (Takayama 2).
2. If it is desired to heat the slide, there is no danger of overheating as there is in the case of haemin crystals.
3. The crystals are large, easily seen, and are of a very characteristic appearance and colour.
4. The nature of the crystals may be confirmed by means of the spectroscopie.

We wish to thank Professor Littlejohn for the help and advice he has given us.

A SIMPLE TEST OF DIAGNOSTIC VALUE IN GENERAL PARESIS.

BY

J. S. HARRIS, M.D. EDIN., D.P.M.,

ASSISTANT MEDICAL OFFICER, WEST PARK MENTAL HOSPITAL, EPSOM.

The diagnosis of general paresis depends upon the recognition of certain mental symptoms, the eliciting of a number of physical signs, and the finding of certain definite changes in the cerebro-spinal fluid. As regards the last named, most reliance is placed on the following four points: (1) a positive Wassermann reaction, (2) a Lange colloidal gold curve of the parietic type (5555543210), (3) an increase in the amount of globulin, and (4) a pleocytosis. Two of these changes—the increase in the number of cells and in the amount of globulin—can be demonstrated with very little trouble, and hence are of the greatest value to the clinician, who is often called upon to make a quick diagnosis. Unfortunately, however, these two alone do not furnish conclusive proof of the presence of general paresis, and delay occurs until the laboratory report on the Wassermann reaction and the colloidal gold curve is at hand. The discovery, therefore, of a test which could be easily and quickly performed and which would be as reliable as the Wassermann reaction would be of considerable importance to the clinician, whether he be a consulting physician or a general practitioner.

In 1923 Boltz¹ first described a test performed on the cerebro-spinal fluid which he claimed would satisfy these conditions, and he stated, as the result of his investigations, that this test (the acetic anhydride-sulphuric acid test) was positive in every case of general paresis and was negative in all other conditions with the exception of certain cases of neuro-syphilis and an occasional case of arterio-sclerotic psychosis. In 1925 Grossman,² using the same acetic anhydride-sulphuric acid test, also found that every case of general paresis gave a positive reaction.

In the present series of cases the cerebro-spinal fluid of 180 patients, suffering from various types of mental disorder, was examined, and the result of the acetic anhydride-sulphuric acid test was compared with the Wassermann reaction, the Lange colloidal gold curve, the amount of globulin, and the number of cells.

Method of Performing the Test.

To 1 c.cm. of cerebro-spinal fluid in a small glass test tube add 0.5 c.cm. of acetic anhydride. Shake the mixture well and then carefully add, drop by drop, 0.8 c.cm. of concentrated sulphuric acid. The test tube is then held up against a white background

and the presence of a lilac tint indicates a positive reaction; a brown-yellow or red-yellow colour is noted if the reaction is a negative one. The lilac colour, characteristic of the positive reaction, may appear immediately after the addition of the sulphuric acid and disappear in a minute or so. Hence it is important to watch the cerebro-spinal fluid closely as soon as the sulphuric acid is added, or a slightly positive case may be missed. In the majority of cases the lilac tint remains for at least five minutes.

The chemistry of this test is not fully understood, but it seems probable that it depends upon the presence of cholesterol in the cerebro-spinal fluid.

Results in 180 Cases Investigated.

Of 92 cases of general paresis the cerebro-spinal fluid showed:

Wassermann reaction positive	92=100%
Acetic anhydride-sulphuric acid test positive	89= 97%
Lange curve of parietic type	81= 91%
Increased amount of globulin	90= 98%
Increased number of cells	91= 99%

Of 5 cases of neuro-syphilis (not general paralysis of the insane) the cerebro-spinal fluid showed:

Wassermann reaction positive	5=100%
Lange curve	4= 80%
Acetic anhydride-sulphuric acid test positive	2= 40%
Increased amount of globulin	4= 80%
Increased number of cells	5=100%

Of 83 cases of other types of mental disorder the cerebro-spinal fluid showed:

Wassermann reaction positive	0=0%
Acetic anhydride-sulphuric acid test positive	1=1%
Lange curve of positive type	1=1%
Increased amount of globulin	5=6%
Increased number of cells	1=1%

Consideration of the above results shows that the acetic anhydride-sulphuric acid test gives a positive reaction in practically every case of general paresis (97 per cent.). Of the three exceptions one was an undoubted case of general paresis with the typical mental symptoms, well marked physical signs, and positive cerebro-spinal fluid findings. The other two cases, however, were by no means typical, and were probably very early cases in which there were few mental changes, some physical signs, and a slightly positive Wassermann reaction in the cerebro-spinal fluid. In another case, a well marked general paresis, the Wassermann reaction of the cerebro-spinal fluid and the Lange curve were found to be negative on the first examination, but the acetic anhydride-sulphuric acid test was strongly positive and the amount of globulin and the number of cells were slightly increased. A second specimen of the fluid was examined a fortnight later, and this time a very faintly positive Wassermann reaction (+3) was obtained; the cells and globulin were slightly increased, the Lange test was negative, and the acetic anhydride-sulphuric acid test was again strongly positive. In this case, therefore, the acetic anhydride-sulphuric acid test was more sensitive than the Wassermann reaction. The degree of positivity of the acetic anhydride-sulphuric acid test in cases of general paresis does not vary directly with that of the Wassermann reaction. Thus certain cases with a faintly positive Wassermann reaction in the cerebro-spinal fluid gave a strongly positive result with the acetic anhydride-sulphuric acid test and vice versa. In a number of instances the cerebro-spinal fluid was obtained from general paralytics who had undergone a course of malarial treatment. In these it was found that although the Wassermann reaction had in most cases become less strongly positive the acetic anhydride-sulphuric acid test showed no change. Compared with the Lange reaction in general paralytics the acetic anhydride-sulphuric acid test would appear to be more sensitive and more reliable, since a positive result with it was obtained in 97 per cent. of these cases, as against 90 per cent. in the case of the Lange test. In cases of neuro-syphilis (not general paralysis of the insane) the Wassermann reaction was positive in all, the acetic anhydride-sulphuric acid test only in 40 per cent. In the 83 other cases which were investigated (cases of epilepsy, manic-depressive psychosis, senile dementia, dementia praecox, alcoholic and arterio-sclerotic psychoses, etc.) only one case, a patient suffering from senile dementia, gave a faintly positive reaction with the acetic anhydride-sulphuric acid test.

Summary.

As a result of these investigations it would seem justifiable to draw the following conclusions:

1. The acetic anhydride-sulphuric acid test on the cerebro-spinal fluid of cases of general paresis is positive in almost every case (97 per cent.), and hence is almost as reliable as the Wassermann reaction in this condition.
2. It is negative in almost every other type of mental disorder except certain cases of neuro-syphilis (other than general paralysis of the insane).
3. It is a test which can be performed with great ease and rapidity and hence is of definite value to the clinician.

ON THE SOMATIC ORIGIN OF MALIGNANT DISEASE.

BY

C. R. CROWTHER, M.D., B.Ch.,

SURGEON, DEVON AND CORNWALL EAR AND THROAT HOSPITAL.

THE view of malignant disease here presented is simple, congruous, as it seems to me, with ordinary pathology and ordinary clinical medicine, reconciles easily and naturally the discordant and puzzling results of recent experiment, and, if true, removes most of the obscurity and mystery from the malignant process.

Malignancy and Hyperplastic Inflammation.

Clinicians have long held the opinion that continued irritation will induce cancer. This opinion has been confirmed by exact observation on the effect of various irritants, especially the extracts of tar; by these, as is well known, the disease has been brought on in mice by direct experiment. Now the chief reaction of the body to a chronic irritant is a proliferation of connective tissue and epithelium. This process is commonly called chronic inflammation; it is well seen in the chronic mastitis which so often precedes carcinoma of the breast. Sir Lenthal Cheatele objects to the term "inflammation" as a description of this process; it differs, indeed, in degree and partly in kind from acute inflammation, but resembles it in being a reaction to mild, as the other to intense, irritation; and, like the acute kind, seems to be essentially a vascular and lymphatic reaction, though in acute inflammation the vascular changes prevail, and in chronic inflammation the lymphatic.

Sir Lenthal Cheatele's accurate and careful observations¹ seem to show that this process of hyperplasia may pass almost imperceptibly into an innocent or malignant tumour. He has shown specimens where in a single breast chronic mastitis has developed into fibro-adenoma and different varieties of carcinoma. Dr. Archibald Leitch's experiments on guinea-pigs² lead to the same conclusion. He was able to produce malignant growth in the gall bladder of the guinea-pig, a refractory animal, by means of gall stones, or even sterile pebbles, aseptically introduced. He, too, is quite sure that there is no clear dividing line between carcinoma and simple hyperplasia. "We have," he says, "no means of determining when the heterotopy and irregular growth of the tubular epithelium ceases to be translatable as simple hyperplasia and assumes the definite characters of malignant neoplasia . . . the process is so gradual and the dividing line so imperceptible."

Malignancy not a Property of the Tumour but a Reaction of the Body.

It seems most improbable, as Dr. Leitch remarks, that any toxic agent should have arrived from elsewhere to change so utterly the nature of the growth yet change its habit and appearance hardly at all; nor could any such

agent have been introduced under the conditions of the experiments, nor probably have been present originally in the gall bladder. I would suggest that the malignant alteration is most simply explained if we suppose that the tumour, or hyperplasia of epithelium, does in fact remain unchanged; that the change from innocency to malignancy consists wholly in an altered reaction of the body. At some moment, we will say, the body becomes aware of this mass of cells, regards it as a living intruder, and attacks it with leucocytes and cytolytins. If the epithelial cells are finally surrounded by fibrous tissue the tumour is "innocent"; it is thenceforth disregarded as a foreign body. But if this encirclement fails, the growth is "malignant"; the malignancy, however, is not in the tumour. There is a fatal difference between this and an invading microbe: the tumour is not foreign to the body, but part of it; the cytolytins which are lethal to the tumour cells are lethal also to the cells of the body. Hence the zone of destruction at the periphery of a malignant growth, the corrosion of muscles and blood vessels and nerves; hence also the fretting of the tumour's surface, the metastases, and general cachexia; all this destruction is wrought, if my view is true, not by the juices of the tumour, but by the juices of the body. It is probable that a vicious circle begins, that the tumour cells which are not destroyed are irritated to more rapid growth, and the body thus stimulated to fiercer efforts; however this may be, the whole malignant process seems in this manner quite easily explained.

Practical Tests.

From acceptance of this view it would follow that if the body could be induced to ignore the tumour the whole malignant process would stop; but how to achieve this is not easy to see; the patient might be hypnotized, but hypnotic suggestion must be carried far to induce a leucocyte to slacken its activity; it seems unlikely that this method would succeed. Again, we might inject some chemical body like a vaccine, but of opposite effect, so that the activity of the body against a specific invader would be not stimulated but depressed. Such a chemical body may be invented in the future by bacteriologists. If the body in the part affected could be made anaesthetic by blocking its afferent nerves it seems possible, but not certain, according to this view, that the malignant process would be arrested or retarded. The reactions of inflammation are probably in large measure the result of chemiotaxis, and so would proceed though sensation were destroyed; still, the tumour would be unfelt and vaso-dilatation abolished. The feeble resistance offered by ataxic patients to perforating ulcer of the foot would seem to afford some hope that the malignant process might thus be checked.

I had arrived at this point when I learnt that this experiment had already been tried—deliberately on mice by Dr. Cramer, and by Nature on sundry patients whose cases are recorded by Sir Lenthal Cheatele. Dr. Cramer³ painted a number of mice with an extract of tar, both on the normal skin and on a part deprived of its nervous connexions. Twelve of these mice developed malignant tumours, and it is noteworthy that in every single case the normal skin was so affected. In five mice malignant growth arose also in the denervated area, but so late, in three of these, that it seems almost certain that the nerves of the part had regenerated themselves before growth began. Thus, in all but two of the mice malignant growth was inhibited by the loss of nerves; moreover, in one of these two exceptions the growth of the tumour was slow and malignancy but slight.

It must be admitted that these experiments do not go very far toward the proof of the case. It may be said that if, as seems likely, malignant disease is a reaction of the body cells to irritation, then that reaction might probably fail if the irritation could not be perceived. Nevertheless, with the old view of cancer, malignant proliferation might seem a reaction of cell protoplasm to a local stimulus rather than a reaction of the body as a whole to an irritant; once allow this, and we are fairly launched on the road to my conclusions. Now, Cramer's experiments, though not conclusive, do strongly suggest that malignant disease is a reaction of the body as a whole,

since the growth arises but rarely when the irritated part is first made anaesthetic.

The observations of Sir Lenthal Cheate¹ are more important, since they show the arrest of a malignant process already begun. In some eight of his cases the growth was checked in one direction when the nerve of that part was destroyed by deep malignant ulceration. Thus in one case a rodent ulcer, which had invaded the area of the supraorbital nerve, grew no more that way after destruction of the nerve trunk, though growing freely elsewhere. These cases seem decisive. The ulcers were in vigorous growth, their cells proliferating, and their supposed destructive juices in full activity. Yet these juices, which could destroy and digest normal cells, could not, apparently, destroy those adjacent cells which differed only in the loss of their nervous connexions. We must, therefore, suppose that malignancy is an attribute, not of the tumour, but of the body excited by the tumour.

Sarcoma.

It is probably safe to say that any surgeon at a large hospital sees fifty cases of carcinoma and epithelioma for one of sarcoma. Yet hyperplasia of connective tissue is exceedingly common, being present in every scar and regenerating wound and all chronic inflammation. It is always present, for example, in chronic mastitis. Yet this condition, so prolific of carcinoma, hardly ever gives rise to sarcoma. On these grounds alone it might have been predicted that for the production of sarcoma something more than simple irritation would be required; and recent research seems to show, or suggest, what this further condition may be.

Dr. A. Carrel² in his researches on the Rous sarcoma of fowls has shown that the virus of this tumour is carried in the large monocytes; further, that some of these cells, when treated with the virus, transform themselves into cells resembling agglutinated fibroblasts. When these diseased monocytes are introduced into a healthy fowl they form tumour cells and attract monocytes, which propagate the virus, and are likewise transformed into tumour cells.

Now in the first place these observations show that sarcoma grows in a very different manner from carcinoma, assuming that the Rous sarcoma is true to the type of its kind. For it seems to grow rather by the accretion of extrinsic cells than by the multiplication of the original cells of the tumour. For the rest, no interpretation but mine seems possible. That the virus is propagated by the body's defenders, the leucocytes, Dr. Carrel notes with wonder, but attempts no explanation. But in my view no explanation is needed, for all malignant disease is so produced. So again the specific poison, prepared by the white corpuscles to destroy their fellows, is equally injurious to themselves; they become part of the tumour, and in their turn are attacked by other leucocytes. All goes on exactly according to hypothesis: in a tumour so composed the phenomena might have been predicted. Only one difficulty remains: what condition initiates the tumour, since it seems that simple hyperplasia is insufficient? To find an answer to this, we are perhaps helped by the well known and still more recent work of Dr. Gye and Mr. Barnard.³ Their work is noteworthy chiefly because they claim to have discovered a living ultramicroscopic virus, which is present in the majority at least of the malignant tumours they have examined. Since, however, the characters of the tumour depend not on this but on another, probably chemical, "specific factor," it seems doubtful whether their "virus" can do more than predispose to cancer. Their experiments, as so far published, are obviously too incomplete to allow us to draw definite deductions from them; but if a surmise may be allowed, we may perhaps suppose that the "virus" is simply a cause of hyperplasia, and the "specific factor" the toxin of the leucocytes, which acts, as Carrel has demonstrated, to generate the vicious circle. How a sarcoma commonly begins is doubtful; it may be that a blow, by injuring the fibroblasts in a simple hyperplasia, will lead to an attack on this group of cells, as a foreign body, by the leucocytes.

Summary.

My conclusions may be summarized as follows:

1. Malignancy is not a property of cancerous tumours, but a suicidal reaction of the body to an innocent hyperplasia.
2. The reaction is suicidal because the hyperplastic cells are really part of the body, and the specific poisons generated to destroy the tumour are almost equally poisonous to the body at large.
3. Sarcoma probably differs in its nature from carcinoma; here the diseased process seems more complex, but the essential nature of malignancy is probably the same.
4. It follows that if the body can be led to disregard the tumour the malignant process will stop, and the patient will be cured, save that the original hyperplasia will remain.
5. It seems possible that this result may be achieved by blocking the afferent nerves of the part.

RECTUS TRANSPLANTATION IN THE TREATMENT OF VENTRAL HERNIAE.

BY

H. C. WARDLEWORTH NUTTALL, F.R.C.S.,

HONORARY ASSISTANT SURGEON, ROYAL INFIRMARY, LIVERPOOL.

THE difficulties of obtaining a "radical cure" in large ventral herniae are well known, and from time to time various new principles have been suggested. Silver filigree, overlapping of tissues, lacing with fascial grafts, etc., have all given good results in suitable cases. There are objections, however, to all, and not one of them is suitable to all cases. Any alternative may be of value when other methods are not entirely satisfactory, and I venture to submit the method of shortening, overlapping, or transplanting the recti as a useful adjunct in the treatment of these cases.

The operation may be briefly described as follows: A transversely curved incision, convex downwards, about six inches long, is made just above the pubis, and the skin and fascia dissected upwards and downwards to expose the aponeurosis. The dissection is carried downwards to expose the anterior surface of the pubic bones and the symphysis. The recti muscles are detached from the pubes and can be shortened if required by making a tuck; they are then sutured to the symphysis, or can be overlapped and sutured with kangaroo tendon to the pubes after drilling holes in the bone. During this procedure the patient's shoulders should be raised so as to relax the muscles. In dealing with an umbilical hernia the sac would be exposed in the usual manner and the peritoneum sutured. The recti could then be overlapped and sutured through a pubic incision before closing the umbilical incision.

This method appears to be specially useful in mid-line herniae through scars below the umbilicus, though it would also be applicable to cases of divarication of the recti and some cases of umbilical herniae. The following case illustrates the method.

A widow, aged 57 was sent to me on April 9th, 1925, by Dr. C. H. Ross Carmichael. In 1903 she had been operated on for some gynaecological trouble by a mid-line infraumbilical incision. The wound healed normally, but about seventeen years later she noticed a swelling appearing in the scar.

In 1921 an operation was performed to cure the hernia; before she was discharged from hospital, however, a recurrence was noticed, and a second operation was performed. She "felt the lump coming back again not long afterwards," and a third attempt was made in 1922, but recurrence took place a few months later.

When I saw her the hernia was about the size of the foetal head and was hanging down over the symphysis pubis. The

skin covering it was thin and atrophic and showed the vertical scar of the previous operations. Partial reduction of the hernia was possible, and the opening in the aponeurosis could then be felt; it admitted three fingers, the lower margin of the opening being formed by the symphysis pubis.

Operation.

On April 11th, 1925, I operated, making transverse elliptical incisions round the hernia, the convexity of the lower incision being just above the pubis. The neck of the sac having been opened, the contents, consisting of omentum and transverse colon, were freed and returned to the abdomen. The superfluous sac was cut away and the peritoneum sutured. The edges of the recti were now exposed and the anterior layer of the sheath dissected up on either side. The dissection was carried downwards so as to expose the symphysis and the pubic bones. The recti were shortened by making a 1½-inch tuck in each, and they were then separately sutured to the pubis with kangaroo tendon so that they overlapped each other; the overlapping of the sheath was carried to the upper limits of the wound when retracted; for this seven or eight interrupted mattress sutures of catgut were used. A small drainage tube was left in the superficial tissues for twenty-four hours. The wound healed by primary union. On April 23rd she commenced abdominal exercises in bed. These consisted in lying on the back and raising the extended lower limbs on the trunk and then raising the trunk without using the hands. These exercises were carried out several times a day until tired. The patient began to get up on April 30th, and was discharged on May 8th.

I saw her on November 25th, and found no signs of recurrence. The abdominal wall was strong and there was no bulge when she raised the extended legs on the trunk.

The interesting feature in this case was the proximity of the neck of the sac to the symphysis, which actually formed one of its boundaries.

Seven months is too short a time to decide the value of the operation from the point of view of recurrence, but on general grounds it is certainly encouraging and appears worthy of trial in suitable cases.

TREATMENT OF CHRONIC VARICOSE ULCER.*

BY

A. P. BERTWISTLE, M.B., CH.B., F.R.C.S.ED.,
LATE RESIDENT SURGICAL OFFICER, GENERAL INFIRMARY, LEEDS.

REMEDIES for chronic varicose ulcer are many and various. For some of these specific virtues have been claimed, but their indiscriminate employment soon leads to disappointment. Full consideration should be given to conditions in each case, and the treatment modified as circumstances vary.

The following cases, which recently came under my care, illustrate this; in two the results were especially satisfactory. The point to be emphasized is the rapid relief of pain which occurred in all.

CASE I.

A spare woman, aged 82, had an ulcer on the lower third of the leg, which had been present for two years. There were varicose veins in both legs. She had been in a large hospital in London for eleven weeks, during which time the ulcer had been fomented continuously. She left hospital on being told amputation was the only treatment possible. She had become very weak as the result of intense pain, especially at night. The ulcerated area measured 12 square inches, and consisted of a main and two outlying portions; it was raised at least half an inch above the surroundings, and was adherent to the bone. For its description Erichsen's definition of a "weak" ulcer cannot be bettered: "The granulations are high and flabby, with a semi-transparent appearance about them, and rising in large exuberant, gelatinous, reddish-looking masses above the surface of the sore. The granulations have a feeble vitality, and readily slough. Such not uncommonly occur from emollient applications having been continued too long." A silver nitrate stick was applied to the edge of the ulcer to destroy these granulations, and gauze, soaked in a saturated solution of picric acid, was placed on the surface. The whole was carefully strapped to prevent drying, as far as possible.

After the first few hours she had no pain, and slept well that night for the first time for months. The ulcer was dressed twice similarly on alternate days, after which the picric acid was replaced by iodoform powder, the silver nitrate being continued. In ten days the surface of the ulcer was level with that of the surrounding parts, and was covered with thin skin. This skin broke down, ex- , however, were now not heaped up. , and boric ointment, spread on lint. hole was covered with thin skin, which ickness. At one time some eczema appeared, but it soon responded to bismuth

powder. She now wears a crêpe bandage. Medical treatment consisted in the exhibition three times a day of a mixture containing 10 grains each of sodium bicarbonate and potassium iodide, with infusion of gentian. Her general condition began to improve immediately with the relief of pain. The cure was all the more remarkable as, although she spent most of her time on a couch, she persisted, when so disposed, in walking about, whereas in hospital she had been confined to bed.

CASE II.

A hard-working woman, aged 49, treated as an out-patient of the London Dispensary, Fournier Street, E., had an ulcer over the tibia two inches from the malleolus, two inches in diameter, which had been treated for many years. The ulcer was depressed, its edges hard and punched out, and its surface glazed and exuding watery fluid. It was fixed to the deep structures. The edge of the skin margin was touched with silver nitrate stick and the surface of the ulcer dusted with iodoform. Gauze and wool were applied and the whole carefully strapped; in a week the edge of the ulcer had become shelving, had lost its induration, and was no longer fixed to the bone. After some three hours' smarting after the dressing, pain had almost entirely disappeared. Her health steadily improved with the alleviation of pain, the same treatment being continued for six weeks. She had the same mixture as Case I. Recently she was able to spend ten days in bed, which completed her cure. She now wears a crêpe bandage.

CASE III.

A business man, aged 65, had had extensive phlebitis in both legs many years ago, and ulcers for about ten years. On the left side were three—two inches, three-quarters of an inch, and half an inch in diameter—on the outer side of the lower third of the leg, resembling that of Case II. On the right internal malleolus was a painful ulcer, neither raised nor depressed. Both legs were greatly swollen, hard, and somewhat oedematous. The same treatment was instituted as for Case I, but unfortunately bismuth had to be substituted for iodoform, as the latter nauseated his wife. Pain was relieved to a large extent, and the patient's legs became more supple. It was aggravated by long standing or cold weather. He is unable to "lie up," but the ulcers have become steadily smaller.

CASE IV.

A Russian Jewess, aged about 60, had an ulcer six inches in diameter over the lower part of the tibia. It was difficult to ascertain how long it had been there—many years, however. The whole leg was enormously thickened. The treatment as for Case II was carried out for six weeks, when she died of cerebral haemorrhage. The ulcer was then only one and a half inches in diameter.

Treatment in these cases resolved itself into that of:
(a) the veins, (b) the ulcer.

The Veins.—The patient should stay in bed, or, if this is impracticable, the leg should be kept up as much as possible and a crêpe bandage worn. The latter is preferable to an elastic stocking, which is expensive and difficult to put on over a dressing; moreover, it must interfere with the blood circulation on the surface of the ulcer.

The Ulcer.—Applications were chosen for the following reasons: (1) Reduction of sepsis is the main objective of all. For proliferating types picric acid has been found to be of the greatest service on several occasions. It possesses considerable powers of penetration, is not irritating, and does not cause much exudation. Iodoform is invaluable in depressed ulcers, having great penetrating powers and being a deodorant, though, as in Case III, it may nauseate certain individuals; peroxide fomentations may be employed if sloughs are present. (2) Stimulation of the skin edge may be done with silver nitrate; when the sepsis is reduced emollient preparations, such as ung. ac. borici, are indispensable. It is astonishing to observe how rapidly an area becomes covered with skin when all papillae must have disappeared years ago (see Case I); such a dressing gives admirable protection against damage to this thin skin. (3) Destruction of granulations goes hand in hand with elimination of sepsis; it is assisted by silver nitrate cauterization. (4) If a cure is to be effected the thin skin must be kept moist and supple; evaporation is best prevented by careful strapping. (5) In protection from trauma strapping forms the best preventive. (6) Of drugs given for alleviation of pain, iodides internally and the iodoform externally may have some action on the bone. Whether this is so or not, the most striking feature of all the cases was the relief of pain.

Memoranda: MEDICAL, SURGICAL, OBSTETRICAL.

SUPERNUMERARY BREAST.

The following case is of an unusual type, and seems to be of sufficient interest to be placed on record.

An Arab woman of the Northern Sudan, aged 25 years, came to hospital complaining that the appendage seen in the accompanying photograph inconveniently pained her when washing.

It was attached to the skin over the second right intercostal space, the base of attachment stretching from the right mammary line to almost the mid-line. It was 2.6 cm. long, and had a proper nipple. The lower third had the feel of breast tissue; and this was confirmed on removal, when a small amount of glandular tissue (with alveolar glands) and a number of ducts leading to the nipple were found inside. Below the normal right breast and in the nipple line were two tiny rudimentary nipples. On the left side nothing abnormal was noted.

As the woman had had no children, there is no proof that the third breast was capable of functioning.

I am indebted to the Director, Sudan Medical Service, for permission to publish this case.
A. CRUICKSHANK, M.B., Ch.B.,
Sudan Medical Service.

Khartoum.

MALIGNANT THYROID TUMOUR OF THE MANUBRIUM STERNI.

The following case is worthy of record as the malignant thyroid mass in the manubrium sterni existed without any clinical evidence of disease of the thyroid gland. The true nature of the tumour could not be ascertained before a small portion was excised for microscopical investigation.

A single woman, aged 73, noticed a small "lump" in the centre of the manubrium sterni about a year ago. It caused her no pain or inconvenience, but gradually enlarged in all directions, and especially towards the suprasternal notch and the left sternoclavicular joint. She stated that two months before she applied for treatment the swelling had become definitely smaller and harder, so that she hoped that it would eventually disappear; it had grown rapidly during the last fortnight. She had no cough, dyspnoea, or dysphagia; neither had she lost weight during the last two or three years.

There was no history suggestive of syphilis, and the Wassermann reaction proved to be negative on two occasions. Two enlarged glands were to be felt in the anterior triangle of the neck on a level with the thyroid cartilage, and another just below the angle of the lower jaw on the left side. They were small, elastic, and freely mobile, and were considered to be inflammatory in nature. The thyroid gland presented no clinical abnormalities; there were no nodular or indurated areas to be made out; it moved freely on deglutition, and on the trachea. The thyroid gland was distinctly separate from the tumour in the sternum. The pupils were equal and dilated; there was no wasting of the upper extremities; the pulses were synchronous; and there was no clinical evidence of disease in the thorax, abdomen, or pelvis.

The tumour itself occupied the upper two-thirds of the manubrium sterni and bulged forwards laterally towards the sterno-clavicular joints, and into the suprasternal notch; it measured 3 inches from side to side, and 2½ inches in the vertical plane. Large veins could be seen coursing over the swelling, and outwards over the right clavicle. The skin in this area showed no signs of inflammation, and was freely movable over the tumour. The growth was inseparable from the bone, and although hard and nodular in places it was distinctly cystic in others. Visible pulsation could be made out, but this was transmitted from the aorta, and not of the manubrium sterni was "eaten away" (eroded) by the tumour. As the clinical findings could throw no light on the nature of the swelling, a small portion of it was removed under local anaesthesia, and submitted to Dr. Robert Donaldson for microscopical investigation. He reported that the tissue was "malignant thyroid."

Two points appear to me to be worthy of note:

- (1) That a large thyroid metastasis can exist without any clinical evidence of cancer of the thyroid gland.
- (2) That the temporary retrogression which occurred in this growth might possibly have been due to a partial thrombosis of some of its feeding vessels.

RODNEY MAINGOT, F.R.C.S.

LEEDS, W.L.

COMPLETE INVERSION OF THE UTERUS.

Complete inversion of the uterus is, perhaps, a sufficiently rare complication of labour to warrant the recording of the following case.

On September 10th, 1925, I was called to see a native woman who, I was informed, had given birth to a child the day before, but "the after-birth had not come away." Expecting to find the ordinary retained placenta, I hurried to the village, some eighteen miles away, by a good cycle track.

On entering the little grass hut in which the labour had taken place, I found myself confronted with what I can best describe as a "living chain" made up as follows: (1) an old woman, holding in her arms (2) her great-grandchild, a healthy female infant, born about thirty hours previously; it was still united by (3) a shrivelled cord to (4) a complete placenta lying on the mud floor of the hut, and connected in its turn by a few shreds of membrane to (5) a completely inverted uterus, surrounded by swarms of flies, and protruding from the vagina of (6) a native girl about 20 years of age, who was leaning back in the arms of (7) her own mother.

Questioning them as to the history of the case, I accused the patient herself of volunteering "I was just straining to get the after-birth away, when it all came out with a rush." There had been one previous normal confinement, and the present labour had not been unduly prolonged.

My first business, after prayer with the patient and her relatives, was to break the link between the child and the placenta; I heard a suppressed gasp of horror go up from the three women as I snipped through the cord with a pair of scissors. The native custom hereabouts is to burn through the cord with a glowing faggot—an excellent prophylactic against both sepsis and haemorrhage. The membranes were then easily separated from the inverted uterus. An interesting detail was that a small portion of the decidua to which the membranes were still adherent was invaginated on the inverted surface of the uterus, a fact which proved that there had been no traction on the cord or placenta.

The decidua was then disinfected, first with tincture of iodine and then with a dilute lysol, after which reposition was quite a simple business, the uterus returning to position above the closed fist and becoming palpable from the abdomen in the usual situation. It was only after reposition that I discovered what was probably the indirect cause of its posterior aspect. The puerperium was complicated by a very mild degree of infection, from which the patient made a complete recovery.

JULIAN HOYTE, M.B., B.S.Lond.

Katwerwe Mission Hospital, Katanga,
South Africa.

APPENDICITIS COMPLICATING GASTRIC ULCER.

LAST March, when I was house-surgeon to the Chester Royal Infirmary, a boy of 15 was admitted at 11 p.m. with the diagnosis of acute appendicitis. He had worked all that day, but at 7 p.m. had a sudden attack of pain in the abdomen round the umbilicus with vomiting. His last meal was at 6 p.m. The bowels had not been open that day. There was no previous history of any digestive disturbance. He looked very distressed; the temperature was 96° and the pulse 92. The abdomen was rigid all over, but most marked over the epigastrium; maximum tenderness over the right iliac fossa; it was resonant all over; there was no loss of liver dullness. Examination by the rectum gave no information.

Operation.—Under general anaesthesia a pararectal incision was made below the umbilicus. The appendix was found to be large, inflamed, with recent adhesions, and flakes of lymph covering it. There was no pus in the pelvis, but round the appendix region was free fluid, which appeared to be coming down from above. Appendicectomy was performed, and the incision enlarged above the umbilicus. A perforated gastric ulcer was present at the pylorus near the lesser curvature, about one-sixth of an inch in diameter, with an indurated area of a quarter of an inch all round it. The stomach was much enlarged. The ulcer was sutured with a purse-string suture and omentum sutured over it. The boy's condition did not permit of a gastro-enterostomy. A drainage tube was fixed in the lower end of the incision. He made an untroubled recovery.

A few days previously we had admitted a similar case in a man aged 26. A typically inflamed appendix with adhesions was found in connexion with an acute perforated gastric ulcer. In neither case was there a previous history of digestive disturbance. The age of the boy certainly made his case unusual.

CANCER OF THE LARGE INTESTINE.

A SPECIAL meeting of the Proctological Subsection was held on January 13th at the Royal Society of Medicine, when a discussion on the relation of simple tumours of the intestine to cancer was introduced by Dr. CUTHBERT DUKES, pathologist to St. Mark's Hospital.

Dr. Dukes said that the main conclusion to which his studies had led him was that the cancer-producing agent, when it first affected the bowel, acted upon a much more extensive surface than was ultimately occupied by the cancerous tumour itself. In this extensive area certain characteristic changes occurred in the mucous membrane of the bowel before a visible tumour appeared in any one spot. The first sign of cancer visible to the naked eye was, he thought, a crop of simple tumours or papillomas. In one or more of these papillomas true cancer developed and the remaining tumours then retrogressed and might perhaps disappear. Some, however, nearly always remained and might be found after careful search studded over the mucous membrane of the bowel around the cancerous growth. He gave a detailed account of the development and general structure of papillomas and adenomas of the large intestine, and referred to the frequency with which multiple adenomatosis appeared in certain families; the experience of surgeons was that cancer almost always developed in the intestines of sufferers from this disease. Dr. Dukes reported a statistical investigation into the frequency of simple tumours in patients dying from diseases other than cancer of the bowel. In 117 unselected cases in which he had searched the whole large intestine from caecum to sigmoid he had only found an occasional polyp or two in twelve, or less than 10 per cent. On the other hand, in the last thirty-three cases of cancer of the rectum and sigmoid at St. Mark's Hospital, Dr. Dukes had found one or more simple tumours surrounding the cancer in twenty-five, or more than 75 per cent. These small tumours, which were situated on the mucous membrane surrounding a cancer, were best seen if the specimen was examined immediately after removal from the body, pinned out, and washed with warm normal saline solution. They were much harder to find in specimens hardened in formalin, and they were much commoner in small early cancers than in the large ulcerating forms. In all these cases Dr. Dukes had cut sections of the central cancer, of the surrounding papillomas, and of the apparently normal mucous membrane in the vicinity. He showed several photographs of these simple tumours and emphasized the fact that these simple tumours were liable to chronic inflammation round their stalks, a condition which he referred to as "collar catarrh." He showed photographs also which proved that the mucous membrane round the cancer, even where it carried no macroscopic tumours, had a peculiar irregularity which he referred to as a "switch-back appearance." The question as to whether the surrounding papillomas preceded or succeeded the cancer was one which could not be decided with certainty in every case. To help to solve this question Dr. Dukes had made a special note of the presence or absence of mitotic figures in the cells, whether the epithelial cells of the tumour were secreting mucus and whether a well formed stroma was present. The evidence derived from this investigation led him to the opinion that probably some of these papillomas arose as the result of the irritation of the cancerous discharge, but others were almost certainly as old or older than the cancer. The experience gained from a study of tar cancer in animals was suggestive from this point of view, for several pathologists had shown that, after painting the skin of laboratory animals with tar, tumour growth began in isolated, usually minute areas, and not diffusely through the whole zone of application of the tar. About three months after application of tar to the shaved skin it was common to see a crop of simple papillomas spring up on the painted area. Cancerous degeneration involved one of these papillomas in six to

ten weeks, after which the other tumours progressed no further. The evidence which Dr. Dukes brought forward suggested that a similar cycle of events occurred in man, though naturally the initial stage of a crop of papillomas was not often noticed. Dr. Dukes described some very early cancers of the large intestine which he had recently examined. The evidence derived from these, from cases also where cancer was found developing in polypi, and from multiple cancer of the bowel, pointed to the conclusion that in every case a little collection of papillomas preceded a cancer, and that cancer developed as a secondary change in one of these simple tumours.

Sir JOHN BLAND-SUTTON agreed that the evidence adduced by Dr. Dukes proved that the early stages of cancer must be sought in papillomas. Such concentrated study as this justified the existence of the Proctological Subsection, and the present meeting was an important date in the history of the pathology of tumours of the intestine.

Sir LENTHALL CHEATLE said that this new work brought the pathology of intestinal tumours into line with what he himself had already proved for breast tumours. He showed some photographs illustrating the relation of simple and malignant tumours of the breast.

Dr. ARCHIBALD LEITCH expressed complete agreement with the views of Dr. Dukes. He had often observed these papillomas around cancers of the bowel, but had not realized they were so common. His experience with experimental tar cancer made him very willing to agree that such simple papillomas might precede cancer in man. He thought that probably some of the papillomas found round a cancer preceded the malignant tumour and others probably followed it. Multiple carcinomas of the bowel were nearly always associated with multiple papillomas. He pointed out that the frequency of tumours of the bowel increased in passing from the caecum to the rectum, probably due to the irritation of the more fully formed faeces.

Dr. MARSHALL FINDLAY said that cancer of the large intestine, like nearly all other cancers, appeared to follow a period of chronic irritation. These simple papillomas of the large intestine were of great interest because of their resemblance to warts of the skin. He had recently inoculated himself with a Berkefeld filtrate from a cutaneous wart and succeeded in producing warts on his hands, thereby confirming the view that the infective agent was a filterable virus. He thought it likely that the minute papillomas to which Dr. Dukes had referred were also infectious and might be caused by a filterable virus.

Mr. LOCKHART-MUMMERY said he had believed for a long time that cancer developed as an accident to simple tumours, and Dr. Dukes's work had proved conclusively that this opinion was justified. The multiple adenoma condition which had been the starting-point of this research was curious, both because it ran in families and because it was almost invariably followed by cancer. Mr. Lockhart-Mummery reported three family histories of patients suffering from this disease who were attending St. Mark's Hospital at present and who provided striking evidence in support of his views.

Sir CHARLES GORDON-WATSON stated that his clinical experience confirmed the suggestion of Dr. Dukes as to the relation of simple to malignant tumours of the intestine.

Mr. GREY TURNER thought that the occasion marked an important forward step in surgical pathology.

THE MEDICO-LEGAL PROBLEM OF INSANITY.

Two meetings of the Royal Medico-Chirurgical Society of Glasgow were held on December 4th and 11th, 1925, when a discussion was held on insanity from the point of view of the general practitioner; the chair was taken by the President, Professor ARCHIBALD YOUNG, on the first evening, and by Dr. W. A. PRIDE on the second.

Dr. R. O. ADAMSON, putting the point of view of the general practitioner, opened the discussion by enumerating some of the difficulties in the diagnosis and treatment of the various forms of insanity and allied conditions. Insanity should be studied as a symptom, in no way different from other symptoms dealt with by the general practitioner. It should be approached along the familiar

road of careful clinical, physical, and, above all, psychical investigation. The distinction between sanity and insanity was arbitrary; the symptom insanity was the result of disorder in the function and structure of those parts of the brain which determined for each person his psychological status, mental powers, and moral conduct. Insanity was detected by impairment and change in the higher cerebral functions, and the evidence was greatly fortified by the presence of delusions and hallucinations. It was important to establish what insanity was not; it was not a minor psychosis, a neurosis, or a hysteria. The speaker indicated the differential points in these conditions, and then drew attention to the manner in which the insanities presented themselves in general practice, as, for example, those due directly to the presence of visceral disease or gross brain lesions. Having touched briefly upon the insanities of the extremes of life, he referred to the position of the general practitioner in family practice regarding insanity, and emphasized the importance of studying early cases and of treating patients, as far as possible, before certification. Various types of insanity were then considered and illustrative cases described. Reference was made, in conclusion, to the practitioner's responsibility in the matter of testamentary capacity and certification.

Dr. J. H. Macdonald, speaking from the point of view of the asylum physician, made a plea for the earlier diagnosis of insanity and the speedier removal of the patient to the asylum. He did so, not only on the general principle that any disease was more amenable to treatment in its early stages, but also on account of the difficulty of making contact with such patients after the establishment of habits of morbid thought and action. He was of the opinion that in many cases incipient insanity could be definitely checked and the onset of secondary symptoms prevented by appropriate treatment in the early stages. Not only from the individual but also from the sociological point of view, the subject was of the utmost importance. Of 18,398 insane persons in Scotland, only 3,014 were maintained by their relations; the annual cost to the State of the remainder was about £700,000. The speaker referred to the social stigma as being a very real and important factor in influencing a decision against certification, and discussed some of the provisions already in force for the observation and treatment of mental disease in its early stage. The observation wards in the parish hospitals had proved of great service, and the stigma of being "on the parish" might, under new health administration, disappear. Observation wards in a general hospital were not suitable, though more use might be made of out-patient clinics similar to those already attached to some of the general hospitals. He thought that properly organized asylums were, on the whole, the most suitable means of dealing with the problem, but urged the desirability of educating public opinion to regard them as "hospitals for mental disease," into which any individual, whether able to pay for his maintenance and treatment or not, could be admitted as a voluntary patient. Reference was then made to the necessity for providing similarly for after-treatment to prevent relapses. The speaker concluded by considering briefly some of the difficulties arising in connexion with certification.

Mr. JOHN DREUMOND STRATHERN, Procurator Fiscal for Glasgow and the Lower Ward of Lanarkshire, after a brief reference to the difficulties of certification, went on to discuss the problem of insanity as it affected criminal responsibility. There were two distinct classes of case in which acute difficulties arose: (1) Cases of murder or grave crime in which a plea of insanity at bar of trial was raised. (2) Cases of minor crime where accused persons were usually certified under Section 15 of the Lunacy Act, 1862. With regard to the first class of case, it was frequently found that the individual concerned had previously led a normal life and had shown no indication of taint of insanity. Such a prisoner might be examined by different medical men not unfamiliar with questions of lunacy—for example, by the divisional police surgeon within a short time of the commission of the crime; by the prison surgeon; and by mental specialists for the Crown—and no trace of insanity in the prisoner be found. Notwithstanding this, at a later stage, mental specialists, instructed for the defence, would

probably reach a contrary conclusion. This was an unsatisfactory state of affairs, and it was not easy to explain the reason for the conflict of opinion, but so far as the law upon the matter was concerned it was quite plain. An individual was responsible for his acts unless he could show (the onus was upon the accused) that he was unable by reason of mental disease to know the nature and quality of the act he was doing, or, if he did know it, that he did not know he was doing what was wrong. An insane person was held not to be responsible for a criminal act upon the ground that by reason of his state of mind he was incapable of formulating an intention to commit the crime. A criminal intention was essential in all acts of crime. Not only was there complete conflict in medical opinion as to what constituted medical unsoundness in such cases, but very frequently there was actual disagreement among the medical specialists as to the facts elicited on examination. He considered that such a state of affairs was not creditable to the medical profession, and that greater unanimity should be secured if possible. In his opinion the confusion arose from the failure on the part of medical examiners to understand exactly what the law required in order to establish a plea of insanity. The one body of medical men appeared to be applying the legal definition of insanity, whereas those opposed to them were applying varying standards of their own, and regarded a criminal lunatic rather as they would a private patient. With regard to the second class of case, he considered that many accused persons suffered from a temporary insanity or insanity of a mild type from which they would probably recover. Many, on the other hand, were "hall-marked" criminals and dangerous to the lieges—in short, criminal lunatics and potential murderers who should be kept under strict supervision permanently or at least for a prolonged period. Such cases were often certified and confined to an asylum, but were out again in the course of a very few months by the simple expedient of escaping from the asylum or under a certification of soundness by the asylum physician. It was not long before their offence was repeated, and they were again certified and confined to an asylum, only again to achieve their liberty by the same process. There was very marked contrast between the methods followed by the medical profession in dealing with those two classes of case. In his opinion, society was entitled to protection against lunatics of the latter class. Once crime was superadded to lunacy, the point of view of public interest should be paramount and the sentimental interests of the patient and his family should become subservient.

Professor GLAISTER referred to points of difficulty which might arise in connexion with certification, testamentary capacity, *curator bonis*, and criminal responsibility. With regard to the dangers of certification, he was of the opinion that there was comparatively little risk where that duty had been exercised *bona fide* and with reasonable care. But a patient who exhibited some departure from a condition of average normal mental health might be dealt with in another way, apart from certification, provided that the amount of departure did not bring the patient within the limits of certifiability. In Scotland such persons might be placed in a private, unregistered place, as a "home," under a certificate given by a medical practitioner, in accordance with Section 13 of the Lunacy (Scotland) Act, 1886, for a period not exceeding six months. Following a brief reference to the question of testamentary capacity and *curator bonis*, Professor Glaister attached great importance to the subject of criminal responsibility, especially in view of the increasing prevalence of a plea of insanity in cases of heinous crime. The presumption of the law was that every person who had arrived at the age of discretion was sane and was accountable for his actions, unless the contrary was proved. The burden of proof was upon the person setting up a defence of insanity, who was required to prove, not merely some taint of insanity, but the particular and appropriate kind recognized by the law. The speaker then considered in detail insanity and mental disease from the legal point of view, and quoted a number of authorities.

Dr. IVY MCKENZIE, after a brief reference to the facilities existing in Scotland for the treatment of incipient

insanity, proceeded to discuss some aspects of the problem of criminal responsibility. He deprecated the present tendency to establish irresponsibility on the basis of what is known as modern psychological theory. It was no doubt important from the legal point of view to establish a defence, but in so doing the interests of society must not be sacrificed. While admitting the desirability of recognizing the various clinical types and grades of insanity, he thought that the application of the various technical terms and designations, as well as the employment of vague and indefinite phraseology, might, and did, prove confusing in the problem of criminal responsibility. In his own practice, where there was a question of plea at bar of trial, he was not guided exclusively by the legal precepts as laid down by the various authorities. His method of approach in any particular case was to consider first, after a careful examination of the patient as a whole, whether the symptoms presented in the case conformed to any well recognized syndrome; and, secondly, supposing that there had been no question of any crime committed, was the patient a suitable case to be admitted to an asylum? In the case of criminals in prison committed under Section 15 the responsibility of the doctor was even greater. He agreed with the Procurator Fiscal's point of view, and considered that quite a different standard was required from that employed in the first type of case. Here there was an individual who repeatedly committed crimes, such as assault and indecency, on whom punishment had no deterrent effect. These cases should be classified as insane and certified as such. The feeble-minded person could never be a criminal by reason of defect, but by something that he did, some positive harmful act, and the question here should be: was the actual conduct prejudicial to society? The average defective was a very harmless person, but when he acquired vicious habits he might become dangerous and should then be classified as insane and dealt with accordingly.

Dr. D. K. HENDERSON considered that the whole problem of mental disorder and defect, of crime, delinquency, and unemployment in one form or another, had as its unit individuals who, for one reason or another, had been unable to meet the stress and strain of ordinary social life. In order to deal with this huge question at its root an attempt should be made to get into touch with the potentially disordered individual at an earlier stage, beginning in the nursery and paying special attention to the school period. Children's teeth and eyes were carefully examined and looked after, and special classes were provided for cases of mental defect; but was sufficient attention paid to the "problem" child, sensitive and nervous, a dreamer and asocial? The general practitioner should always keep in mind the psychological aspects, even of physical illness, and all such symptoms as "tantrums," sleeplessness, irregularity in regard to food, and nocturnal enuresis, should be treated with great seriousness. The practitioner could also help by urging the value of treatment in a mental hospital, minimizing as much as possible the stigma of certification. He thought that in the past the asylum superintendent had not taken a sufficiently definite attitude towards the problem of the mental health of the community. In regard to the medico-legal side, he believed that the law and medicine were two different subjects, and he did not see how they could ever come to see eye to eye. The law dealt with the crime, while medicine dealt with the criminal; the law therefore was to a certain extent partisan, whereas medicine and medical opinion should be unbiased. Furthermore, it was constantly said that the plea of insanity in criminal cases was now completely overdone, whereas he believed quite the opposite was the case, because he did not consider that the question of mental disorder in relation to crime was sufficiently considered. Far more insane people were convicted and sent to prison than there were sane people who escaped the rigour of the law on the plea of insanity. Dr. Henderson quoted a number of statistics on the basis of which he felt certain that our prisons to-day were loaded with individuals who were in many respects not responsible. He believed, however, that the insanity plea was far too frequently made use of in cases of major crime.

Dr. MARION GILCHRIST, speaking of cases of senile dementia, thought that some provision should be made for such, without having to send them to an asylum. In the homicidal cases she agreed with Mr. Strathern and Dr. Ivy McKenzie that it was much more important to look after the interests of the sane than of the insane, and to protect the sane from homicidal maniacs. She specially thanked Mr. Strathern for what he had said about the punishment of offenders against women and children, and said it was an absolute disgrace to our civilization that these men should be allowed to be in and out of prison, or in and out of asylums, as at present. She considered that it should be quite possible to detain these offenders for life. Dr. Gilchrist concluded by giving some facts about the Purvis case, in which she and Dr. Carswell were sued for £20,000, and she detailed some of the lessons learned by her in the conduct of the case.

Mr. STRATHERN, Dr. MACDONALD, and Dr. ADAMSON then replied briefly to some of the points raised in the discussion.

EMERGENCIES IN EAR, NOSE, AND THROAT TREATMENT.

At a meeting of the Nottingham Medico-Chirurgical Society on December 2nd, 1925, Mr. H. BELL TAWSE delivered his presidential address on some emergencies of ear, nose, and throat work as the practitioner sees them; he prefaced his remarks by assuring Mr. R. G. Hogarth, President-Elect of the British Medical Association, and the local executive committee that the society would do everything in its power to help to make the Annual Meeting of the Association in July next a great success.

Mr. Bell Tawse first of all dealt with the difficulties that sometimes arise in the diagnosis between a furuncle in the external auditory meatus and an acute mastoid, and pointed out that the former might give all the symptoms of the latter and that the two might be combined. He advised the opening of the mastoid cells in all doubtful cases, judging by their appearance whether to go further or not. He urged that practitioners should take every opportunity of teaching the public that earache was serious, and that an immediate examination should be made. He urged strongly that acute otitis media should be treated as a surgical emergency, and be dealt with at once by paracentesis or incision of the drum; if adenoids were present they should be removed at the same time. He described cases to illustrate the fact that serious mastoid disease—even with intracranial complications—did occur with a normal intact drum where the only history of trouble was earache. He discussed the treatment of foreign bodies in the upper air and food passages, and condemned the use of the coin-catcher, probang, and bougie. He added that the use of these instruments had frequently been followed by fatal results, when the patient might have lived even if no attempt had been made to remove the foreign body. The treatment of epistaxis was described and its pitfalls enumerated; the address terminated with an account of the methods of dealing with haemorrhage after tonsillectomy.

PROGRESS IN GYNAECOLOGY.

A MEETING of the North of England Obstetrical and Gynaecological Society was held at Liverpool on December 18th, 1925, when the President, Dr. J. E. GEMMELL, delivered an address on the progress in gynaecology during the last forty years.

Dr. Gemmell, after referring to the ancient history of gynaecology and the contributions of Hippocrates, Aetius, and others, sketched the state of gynaecological teaching and practice in Edinburgh at the time of his graduation in 1885. The only pelvic operations seen by him as a student were perineorrhaphy, trachelorrhaphy, the cauterization of haemorrhoids, and one ovariectomy which was performed by Thomas Keith with much ceremony in an isolated room in the Royal Infirmary. Gynaecology was then a small subject, limited chiefly to out-patient and consulting-room work; it was not free from the taint of quackery, and sometimes provided a target for the shafts of the satirist. In the eighties the peritoneum

was feared, and pelvic infections were but little understood, and were invariably treated on conservative lines. Great credit was due to the early work of Tait and Gillingworth on salpingectomy, for this had led to the replacement of the old methods of colpotomy and prolonged drainage by the modern practice of excision with abdominal closure. In the same way, the use of the pessary had largely given way to surgical procedures in the treatment of prolapse and other displacements of the uterus, and although the value of some of the operations employed for the correction of retroversion was still a matter of controversy, yet with regard to prolapse it was generally agreed that the so-called "Manchester method" of performing colporrhaphy had firmly established itself as the method of choice. Pelvic haematocoele had become a rarity since the adoption of the surgical principle of "going for the bleeding point," but forty years ago such cases were the common result of the expectant treatment of ectopic gestation, whereby the effused blood was either absorbed during a long period of semi-invalidism or evacuated after suppuration by spontaneous rupture into the rectum or vagina. The history of the surgical treatment of fibromyomata was next described, and the President gave his own personal experiences and results of hysterectomy for these tumours. Similarly he traced the steps that had led up to the modern extended abdominal hysterectomy for carcinoma of the cervix, and showed that the Wertheim type of operation had been gradually developed by the efforts of many different surgeons. References were made to the advances in gynaecological pathology, to certain improvements in surgical technique, and to the present methods of preparing patients for operation. The President concluded by saying that the science and art of gynaecology now stood upon a firm basis, and that it should not be forgotten that the pioneer work of ovariotomists had paved the way for successful surgery in the upper abdomen.

A Method of Demonstrating the Ganglia of the Cervix Uteri.

Dr. A. A. GEMMELL (Liverpool), in a note on the uterine ganglia, said that the study of the nerve supply of the uterus was receiving renewed attention, but the function of this nerve supply had been more fully recorded than its anatomy, and nothing had been written about the pathological changes in gynaecological diseases. He referred to the early English work on the subject, and added that most observers agreed now that the uterus was supplied mainly by the sympathetic proper (the white rami from the lower dorsal and first and second lumbar nerves) via the inferior mesenteric ganglion and hypogastric plexus to the ganglia of the cervix uteri and thence to the uterus itself. All authors agreed that there were cervical ganglia, some postulated others in addition. They gave only scanty information as to the site of the cervical ganglia, but placed them at about the level of the internal os. Dr. Gemmell had examined the specimens removed by Wertheim's hysterectomy in cases of carcinoma of the cervix. No definite attempt had been made to determine the presence or absence of intramural ganglia, but in none of the sections examined were any seen. Dissection of the ganglia, even with the aid of dissecting binoculars, was found to be impossible. A block of tissue was cut, centred on the uterine artery, out of the parametrium and including a piece of uterine wall, and the whole of this was examined by serial sections. More recently such blocks had been divided into four and the postero-inferior portions cut serially. The ganglia were always found by this method if they were present, and it appeared that they lay internal to the ureter, posterior to the uterine artery, and at a little distance from the uterine wall. Similar sections were obtained from six patients who died from various other diseases not involving the genital organs; in all cases ganglia were found. The ages of these patients ranged from 7 months to 65 years. It would appear, therefore, that these ganglia were present at all ages as normal structures, and were not appearances produced in the nerves by carcinoma or other pelvic disease.

Dr. FLETCHER SHAW (Manchester) asked whether Dr. Gemmell had examined the parametrium behind the uterus. He had been very much struck by the excessive amount of shock shown by patients when he had enucleated tumours or growths from this region, and had often thought this part must be especially well supplied from the sympathetic system.

Dr. LEITH MURRAY (Liverpool) remarked that an extension of malignancy from the cervix had been observed in these ganglia and along the related nerves; Dr. Gemmell's research might have an importance from that point of view.

Dr. GEMMELL, replying, thought there were some variations in the positions of these ganglia, as in some specimens he had been unable to find them anywhere in the parametrium. There was the possibility that interference with the ganglia might account for the shock following Wertheim's operation. The utero-sacral ligaments and posterior portion of the parametrium had not been examined, since it was thought that there was more chance of finding sympathetic elements along the vessels in this neighbourhood as in other parts of the body.

"Locked Twins."

Mr. MILES H. PHILLIPS (Sheffield) reported a case of impaction of twins, one of the rarest forms of obstructed labour.

The patient was a primigravida, and twins had been recognized by her doctor at an ante-natal examination on September 4th, the foetal heart sounds being easily heard at both sides of the abdomen a week before labour commenced. Labour began on September 11th at 7.30 a.m., the pains being weak and irregular, but by 10.30 a.m. on the 12th the cervix was fully dilated. The contractions were then strong; no progress was made, and Mr. Phillips saw the patient at 12.30 p.m. The uterus was not in tonic contraction, but was contracting so frequently that it was impossible to palpate the foetal parts. No foetal heart sounds could be heard. The patient was anaesthetized and placed in the lithotomy position. A head was visible, low in the pelvis, unduly soft, with a large caput, and the skin peeling. A hand, passed alongside the head, felt a rounded mass—apparently a second head—at the pelvic brim, impinging on the neck of the presenting child. It was impossible to push the second head out of the pelvis, and a tentative pull with forceps on the lower head failed to move it. The first head was obviously beginning to macerate, and so, after perforation, to afford the necessary room, the neck was cut through with curved scissors, the head withdrawn, and the trunk pushed aside. The second head, soft and pulpy, then entered the pelvic cavity, and was easily extracted with forceps. This child was also dead. The children were males, weighing 5½ and 5 lb. respectively. No liquor amnii was seen, and it was not known when the bag of membranes ruptured. The placenta weighed only 1 lb., but otherwise it appeared healthy. It might well be that a relative placental insufficiency had caused the death of the foetuses, either just before or during the not very protracted labour, as it was thought that at least one foetal heart had been heard on the day before delivery. The single chorion showed a central opening about 4 inches in diameter. The amniotic membrane was in two portions, each attached to the root of the umbilical cord, and over a limited area to one another. At some time during the pregnancy this had been perforated.

In the numerous other cases of twin labour with which Mr. Phillips had been concerned two distinct sacs had existed, the second presenting and being ruptured after the delivery of the first child. Such an arrangement would appear to render collision of the two foetuses extremely unlikely. On the other hand, the loss of all the liquor amnii from two communicating sacs would conduce to this very rare complication.

Miss IVENS (Liverpool) had had a case of "locked twins" some years ago in a primigravida. After considerable delay in the second stage the first twin was felt presenting by the vertex, and the second was found lying transversely with its neck very much elongated and stretched across the neck of the first. The transverse twin was dislodged and pushed upwards by the hand in the uterus. The first was then delivered by forceps; the second presented as a vertex and was also delivered by forceps.

Dr. D. DOUGAL (Manchester) referred to a case admitted to St. Mary's Hospitals, Manchester, as a "failed forceps" case. Under anaesthesia it was found that the advance of the first child was obstructed by the head of the second one; delivery was easily effected by pushing the second out of the way. The first child was dead, probably owing to injury during previous attempts to deliver with forceps.

Both children were small and this might account for the second head being able to pass into the pelvic brim and so cause obstruction.

Dr. G. W. FITZGERALD (Manchester) had seen a case where the first foetus presented by the breech and the second was a vertex presentation. The first was born as far as the umbilicus when the patient was admitted to hospital. Investigation showed that the chin of the first was locked on the chin of the second. Liberation of the head of the latter was impossible, and since the first was dead it was decapitated and the delivery of number two easily completed. There was, however, some difficulty in extracting the head of the first foetus.

Professor BRIGGS (Liverpool) stated that in the laboratory of practical obstetrics he had utterly failed in experimentally locking twins, and he was unprepared to accept reports of foetal incidents or complications within the pelvic cavity, or at the brim of the pelvis in the second stage of labour, unless the whole of the hand of the obstetrician had been previously placed within the pelvic cavity.

Vaginal Myoma.

Dr. D. DOUGAL (Manchester) reported two cases of vaginal myoma.

A woman, aged 42, complained of a bearing-down sensation, and when straining during defaecating a mass protruded from the vaginal orifice and had to be pushed back. Examination showed a soft tumour about the size of a tennis ball arising from the lower part of the anterior vaginal wall. Its consistency was soft, like a degenerating fibroid or a cyst with viscid contents. It was easily enucleated vaginally and proved to be a myoma showing early hyaline changes. Recovery was uneventful.

The second woman, aged 29, complained of soreness and swelling in the vagina, and pain on micturition; a yellowish discharge had been present for a fortnight. The vaginal orifice was found to be virginal, being partially closed by a crescentic hymen; protruding through the orifice was a dark red tumour one inch in diameter, tender to the touch, the surface being raw in appearance and covered with muco-pus. Under the anaesthetic the vaginal orifice was enlarged and the tumour removed. It was a lobulated growth arising from the anterior vaginal wall and covered by mucous membrane, except at the lower pole where it had ulcerated through its capsule and given rise to the purulent discharge. The tumour proved to be a myoma, the lower part being enormously vascular and showing inflammatory changes.

Professor BRIGGS (Liverpool) said the physical characters of each specimen suggested a fibroma.

Vesicular Mole with Coincident Chorion-epithelioma of the Vulva.

Mr. W. W. KING (Sheffield) described a case of chorion-epithelioma in which a metastatic growth was present at the vulva during the course of an intrauterine pregnancy.

The patient, aged 33, had had one child ten years previously, since when menstruation had been regular. She was first seen on account of uterine haemorrhage of seven weeks' duration without previous amenorrhoea. Two days previously a haematoma had suddenly appeared at the vulva and the enlarged uterus suggested the presence of a carneous mole. After excising the labial growth the operator was surprised to find that the uterus contained a hydatidiform mole. Histological examination of the vulval tumour showed it to be a chorion-epithelioma of the type described by Ewing as "chorion-adenoma." In view of the reputed low malignancy of this type of chorion-epithelioma, and encouraged by the record of a somewhat similar case quoted by Teacher, in which the patient had made a complete recovery after simple excision of the metastatic growth and evacuation of the uterus, the present patient was advised that radical operation was not necessary. Her subsequent history was as follows. Menstruation was normal during the ensuing three months, when small irregular haemorrhages commenced. Examination showed no sign of recurrence of the vulval growth, and the pelvis was apparently free from growth. It was decided to explore the uterus, and in so doing one tiny vesicle was discovered almost by accident. The presence of this vesicle three months after the evacuation of a vesicular mole was itself suggestive of malignancy, even apart from the growth which had been previously removed from the vulva. Hysterectomy was decided upon, and, on opening the abdomen, two considerable secondary deposits were found in the pelvis. Their removal was impossible, but the uterus and appendages were removed in the hope that the secondary deposits would atrophy. Histological examination showed that the uterine wall was invaded by chorion-epithelioma. In spite of the secondary deposits the patient had remained well during the four years which had elapsed since the operation.

Commenting upon the case, Mr. King emphasized the fact that unless he had found the vesicle in the curettings

he would not have felt justified in removing the uterus, and that there was little doubt that had he not done so the patient would have died of chorion-epithelioma. The case raised the question of the fallacies of a negative report upon curettings in such cases. He related a further case to show how unreliable a diagnostic curetting might be.

This second patient had a vesicular mole evacuated in June, 1925, and three months later she had some irregular uterine bleeding. There were no physical signs of new growth in the pelvis, but it was decided to remove the uterus without a preliminary diagnostic curetting because, in view of the previous case, a negative report would not have been convincing. The uterus was therefore removed by abdominal hysterectomy. No secondary deposits were found in the pelvis or elsewhere, but on cutting into the uterus it was found to be riddled with growth. At only one spot did the growth approach the endometrium, and this was only a tiny microscopic patch which might well have eluded the most careful examination of the curettings. Some of the deposits in the musculature of the uterine wall apparently dated from the time of the vesicular mole, for they were encapsulated. It was interesting to speculate about the factors which stimulated some cells into activity and allowed others to atrophy.

Adenomyoma of Recto-genital Space and Sarcoma of Ovary.

Dr. G. W. FITZGERALD (Manchester) showed a specimen consisting of the uterus with its appendages and a portion of the posterior vaginal wall. The left ovary was represented by the wall of an ordinary ovarian cyst, and the tube was dilated at its abdominal ostium. The right ovary was partly solid and partly cystic, and distension of the abdominal ostium of the tube was seen. From the cystic portion of this ovary tarry fluid exuded when it was opened. There was close adhesion between the posterior vaginal wall and the anterior rectal wall, with a cluster of minute peritoneal cysts around this. The area on the vaginal side was removed, together with the adjacent posterior vaginal wall. Examination of the sigmoid showed one portion with the same induration as was observed in the rectal wall, and a crop of tiny peritoneal cysts which were easily wiped away. A microscopical section from the growth removed with the portion of the posterior vaginal wall showed the essential features of adenomyoma, while another section of the solid portion of the right ovary (in which there was the tarry cyst) showed the essential features of a sarcoma. The patient was aged 33, and was a 4-para; she complained of dysmenorrhoea of four months' duration, a tender lump in the right side, frequency of micturition, and some pain on defaecation. There was no loss of weight.

THE MECHANISM OF DIAPHRAGMATIC RESPIRATION.

At a meeting of the Brighton and Sussex Medico-Chirurgical Society on January 7th, Mr. H. J. WALKER, the President, in the chair, Sir CHARLTON BRISCOE, Bt., physician to King's College Hospital, gave an address entitled "Some points concerning the mechanism of respiration."

Sir Charlton Briscoe suggested that in certain pathological conditions the defect was probably due to an insufficient expansion of the lower lobes of the lungs. Such conditions arose as the result of pleurisy, pneumonia, "functional" disorders—especially anxiety neurosis—abdominal operations, and rapid reduction of weight. He stated that it was a mistake to regard the diaphragm as a muscle which acted uniformly, or which remained at a constant level in the thorax. It had been shown by animal experiments that the earliest contraction occurred in the crus, and, further, that by flexing or extending the spine the relative contractions of the crus and the costal portions of the diaphragm could be varied. These experiments had confirmed the deductions drawn from clinical observations. In normal individuals the height of the diaphragm, relative to the chest wall, varied according to the posture of the individual, although there might be an almost equal amount of abdominal protrusion, this being taken as a rough indication of the descent of the diaphragm. These variations in height were shown by x-ray tracings taken during the ordinary antero-posterior

examination, and also by estimating the points at which the diaphragm ceased to be in contact with the costal pleura. The heights and movements of the diaphragm were correlated with kymographic tracings of the movements of the thorax, epigastrium, and hypogastrium. The best estimation of the relative height of the diaphragm was obtained by taking a tracing of the upper surface in quiet inspiration and expiration, and a further tracing to record the descent of the diaphragm as the result of a forced inspiration. These records showed that in ordinary circumstances the diaphragm was higher in the thorax in the supine posture than when reclining at an angle of 45 degrees, or when standing. In this posture the inspiratory depression of the diaphragm and the protrusion of the epigastrium might be as great or greater than that recorded when erect or reclining. The highest level of the diaphragm was recorded in a case of paraplegia involving the eighth thoracic segment. It was next shown that in cases of paraplegia from a lesion high up in the dorsal spinal cord or the lower thoracic cord the lower lobes of the lungs were completely deflated. A similar but less complete degree of deflation occurred in individuals who were kept in the supine posture, as, for instance, after abdominal operations. It was also found in cases of unilateral phrenic paralysis, pericarditis, the so-called diphtherial diaphragmatic paralysis, and certain other conditions. A table was then shown of cases in which deflation of the lower lobe occurred, the common factor of which was that the diaphragm was found to be high in the thorax, although there might be a considerable degree of inspiratory descent. The conclusion was drawn that the expansion of the lower lobes depended, not on the movement of the chest, nor on the degree of movement of the diaphragm, but on the low position of the diaphragm in the thorax. The clinical conditions were then considered, in which incomplete expansion of the lung occurred. The symptoms arising were generally "asthenic" symptoms, such as shortness of breath, panting, rapid respiration, failure of respiratory response to effort, tendency to fainting, the persistence of cough with some expectoration, general lack of well-being, and an aching in the neck, arms, and chest, especially on exertion. The final section of the lecture was devoted to the means of correcting this condition by training in the voluntary control of abdominal protrusion; x-ray tracings showing the results of this measure were exhibited. The effect of making the patient lie on the side opposite to that on which the diaphragm was affected was pointed out, and slides were shown to demonstrate the effect on the diaphragm of this posture. The effect of restriction of movement of the lower ribs was illustrated by kymographic tracings, and the beneficial effects of restoring the normal diaphragmatic movements were indicated. This method was particularly valuable in removing the last remains of infected material in the lower lobes after bronchitis and pneumonia.

ANTE-NATAL WORK IN GENERAL PRACTICE.

At a meeting of the Newcastle-upon-Tyne and Northern Counties Medical Society on January 7th, Dr. NEN MACLACH presiding, Dr. L. M. WEEKS delivered an address on the importance of pre-maternity work as applied to general practice.

Dr. Weeks said that for the past two and a half years he had applied in general practice the same routine method of investigation and examination of pregnant women as was used in the pre-natal clinics of the Princess Mary Maternity Hospital and other places. His paper dealt with the results and experience he had obtained thereby during this time. He first drew attention to the problem of educating patients to seek advice early, and, if possible, before the third month of pregnancy. Any prejudices against examination were easily overcome, and women always returned voluntarily in a second pregnancy if adequate care and interest had been shown in the pre-maternity consultations for the first. In the early months a pelvic examination was not necessary unless there was a history of frequent miscarriages in a woman with a

negative Wassermann reaction, or in cases of slight haemorrhage suggesting ectopic gestation. The first consultation should be devoted to a routine inquiry about previous illnesses, the previous menstrual history, the history of previous pregnancies, and any present symptoms, followed by examination of the heart, lungs, and urine. This was the time to give the woman advice and general rules for the rest of pregnancy, with a warning to report such symptoms as would suggest preeclampsia, placenta praevia, or eclampsia. Any such symptoms should receive special attention. Monthly examinations of the urine should be made up to the eighth month, when the position of the foetus should be determined by abdominal palpation. A breech, transverse, or occipito-posterior presentation should then be corrected to a vertex by external rotation, and maintained by pads and binder. In these cases another examination should be made two weeks later, and special attention should be paid to the type of case with the head high above the pelvic brim at this stage, freely movable, and not descending. Some interference with the lower uterine segment should be suspected in these—such as contracted pelvis, false promontory, fibroids, or placenta praevia—when a pelvic examination should be made and the true conjugate measured. The important deformity "funnel-shaped pelvis" should also be looked for. The great value of these pre-maternity examinations was that the type of case likely to require Caesarean section or other special treatment could be recognized before the patients came into labour. Cases were quoted from maternity hospital work illustrating how routine pre-natal examinations might have saved many of the "failed forceps" cases admitted in emergency for Caesarean section.

Mr. H. HARVEY EVERS, in a short address on albuminuria during pregnancy, drew attention to the importance of the subject in relation to ante-natal work, and gave briefly the results of biochemical investigations in relation to diagnosis, prognosis, and treatment. The salicyl-sulphonic acid test for albumin was first demonstrated, and its value and advantages for routine use were pointed out. Albuminuria during pregnancy was classified as symptomless simple albuminuria, the nephritic toxæmic type, and the true "pregnancy kidney" type, or pre-eclamptic toxæmia. The differentiation of these three types was then described on clinical and chemical grounds, tables of the usual chemical findings for normal pregnancy, symptomless albuminuria, true nephritic types, and pre-eclamptic types being shown. Results of blood urea estimations and the urea concentration and diastase tests were demonstrated and their values discussed. The great assistance to be obtained from readings of the systolic blood pressure was emphasized. The immediate and remote prognosis were then discussed, and the material differences between the purely "pregnancy kidney" type and the "chronic nephritic" were pointed out, together with their bearings upon the treatment. The value of the chemical findings, supplementing careful clinical observations, in guiding the lines of treatment was indicated. In "pregnancy kidney" cases there was little call for active interference with the pregnancy, as the great majority of these cases did quite well on purely medical treatment. Only in the rare cases which became progressively worse, clinically and chemically, under treatment, should active measures be adopted. In chronic nephritic cases, on the other hand, chemical and clinical evidences of progressive renal failure indicated the advisability of emptying the uterus. The value of blood urea estimations and the urea concentration test in this connexion was pointed out. Albuminuric retinitis was an absolute indication for emptying the uterus.

Dr. HERBERTSON spoke with enthusiasm of the help he had received by the routine ante-natal examination of 150 cases in a general industrial practice. Any scepticism or suspicion on the part of the patient was quickly swept away, and he had no hesitation in saying that the adoption of a definite pre-maternity scheme in general practice was one of the greatest advances in preventive medicine.

The rest of the meeting was devoted to a demonstration of clinical cases, medical and surgical.

Reviews.

HISTOLOGY OF THE ENDOCRINE ORGANS.

The Histology of the More Important Human Endocrine Organs at Various Ages,¹ by Dr. EUGENIA R. A. COOPER, contains an accurate and careful description of the histology of the pituitary, suprarenal, thyroid, parathyroid, and thymus glands, at all periods, from early foetal life till old age. The textual descriptions are supplemented by numerous illustrations. From her comparative study the author has drawn a number of conclusions which are of equal interest to the physiologist and pathologist. An accurate description of this nature makes it possible for the pathologist to say with some certainty which variations indicate pathological conditions, and which are merely physiological variations. The most striking facts elicited are that the endocrine glands as a whole assume their adult histological characters remarkably late, and in some cases not until after birth. Moreover, the glands show considerable histological changes at various periods after birth.

The detailed description here given of the development of these glands reveals a number of points of physiological interest. For example, the author states that in none of the pituitary glands examined, whether foetal or post-foetal, did she find any evidence of a cavity in the hypophyseal stalk. This observation at once raises the doubt whether in man the posterior lobe of the pituitary gland can secrete into the third ventricle. This is a matter about which there has been considerable discussion. Dr. Cooper concludes from a study of the suprarenals that the cells of the abdominal sympathetic ganglia and of the suprarenal medulla both originate from a common stock of sympatho-chromaffin cells, and that these latter emigrate through the cortex of the suprarenals to take up their final central position, and that this process is not completed until after birth. She has studied the amount of colloid in the vesicles of the thyroid at various ages and has thus estimated the secretory activity of the thyroid, on the assumption that the less the colloid the more rapid the secretion from the gland. She concludes that during foetal life the thyroid produces more secretion than it excretes, and thus accumulates a reserve store. This store is rapidly expended after birth, but in later infancy and childhood production keeps ahead of expenditure and a fresh store of colloid is accumulated. This store is completely exhausted at adolescence, and, according to her observations, the structure of the gland at this age period shows a striking resemblance to that seen in exophthalmic goitre. After adolescence the task of the thyroid is easier and production keeps ahead of expenditure for the rest of life, and the store of colloid is maintained; it is this which gives the adult thyroid its well known vesicular appearance.

These are only a few examples of the numerous interesting observations in the book, but they are sufficient to show that it will be of great value to anyone who wishes to understand the functions of the endocrine organs. We hope that the author will pursue her studies and give a similar account of the other endocrine organs.

A MANUAL OF HYGIENE.

The appearance of *A Manual of Hygiene*,² by Sir WILLIAM HAMER and Dr. C. W. HUTT, the medical officer of health for Holborn, signalizes the retirement of the former from the post of medical officer of health to the London County Council. A note on the back of the title-page tells us that the book is based on Hamer's *Manual of Hygiene*, which was published in 1902. It seems to be much the same as that work, with such omissions, additions, and rearrangement as might be expected in a revised edition after a lapse of twenty-three years; it should be judged from that point

of view. Thus we find that the greater part of the chapters on air, water, soil, food, the collection, removal, and disposal of refuse, dwellings, schools, and hospitals, infection and immunity, infectious diseases, disinfection, and vital statistics, constituting the bulk of the volume, is practically the same in wording and arrangement as the corresponding chapters in the 1902 volume, with such revision as may have been rendered necessary by progress in scientific knowledge or legislative enactments. In the chapter on water, for example, somewhat more space is given to bacterial examination and standards, and in that on food accessory food factors are discussed. In the chapter on infection and immunity, the opening section dealing with parasites has been omitted, and a short paragraph on anaphylaxis introduced, with some curtailment of the lengthy discussion in the previous volume on the hypotheses of Ehrlich and others in regard to immunity. In the chapter on infectious diseases, while much of the original writing has been retained, there has been some rearrangement and a few omissions and additions. Beri-beri is no longer included among the infectious diseases, but has two pages allotted to it in the chapter on food. Cancer has been relegated to the chapter on vital statistics; and tuberculosis is given a chapter to itself. New diseases added to the chapter on the infectious diseases include encephalitis lethargica, poliomyelitis, jaundice, Vincent's angina, and trench fever. A useful addition at the end of the chapter is a description of verminous conditions. Greater detail in regard to chemical disinfectants is introduced into the chapter on disinfection.

There is scarcely any change or new matter in the chapter on vital statistics, but some of the elaborate actuarial calculations included under tests of longevity have been omitted, although those in connexion with life tables have been retained. The subject of cancer, as already noted, has been tacked on to this chapter. In the 1902 edition no charts were included in it. In the new manual there are three—one showing the marriages, births, deaths, and infant mortality rates in London from 1841 to 1923; another the deaths from diarrhoea and enteritis under 2 years of age from 1862 to 1920, and the infant mortality from 1858 to 1920; the third chart is in connexion with life tables, and indicates some changes in the conditions of life as shown in the London life tables of 1841-1922.

Four new chapters have been introduced, portions of which are taken from the old volume. The late Dr. James Niven contributed the chapter on tuberculosis. Mr. Kenneth Walker and Dr. Kenneth Fraser have written chapters respectively on venereal diseases and school hygiene; and there is a chapter on maternity and child welfare. The interesting opening chapter of the 1902 volume, however, on the rise and progress of preventive medicine, has been omitted. The final chapter, on sanitary administration and sanitary law, revised by Dr. Niven, is among the most satisfactory and valuable in the book, especially as the volume has been designed to meet the needs of those seeking a diploma in public health. As such it is a useful guide to students; but one gets the impression that it has not been so carefully prepared as the older volume as regards the arrangement of headings and subheadings. Beri-beri, for example, is lost to sight under the central heading of rickets; and it might have been expected that cancer would have formed a chapter of itself, in the same way as tuberculosis and venereal diseases, instead of being included under vital statistics. The amount of space given to the different subjects also seems disproportionate. Some are too full and detailed, others too limited; and matter might without loss of value be cut off one subject and so permit of space being available for useful additions to another. The general get-up, printing, and binding leave nothing to be desired, and the volume is of a size that is easily handled.

DISEASES OF CHILDREN.

The twelfth edition of *The Diseases of Children*,³ by the late Sir JAMES GOODHART, has now appeared, edited, like the last, by Dr. STILL. The book first appeared in 1885,

¹ *The Histology of the More Important Human Endocrine Organs at Various Ages*. By Eugenia R. A. Cooper, M.D. Oxford Medical Publications. London: Humphrey Milford, Oxford University Press, 1925. (Demy 8vo, pp. xiii + 119; 61 figures, 1 coloured plate. 12s. 6d. net.)

² *A Manual of Hygiene*. By Sir William H. Hamer, M.D., F.R.C.P., D.P.H., and C. W. Hutt, M.D., D.P.H. London: Methuen and Co., Ltd. 1925. (Demy 8vo, pp. xi + 821; 94 figures. 30s. net.)

³ *The Diseases of Children*. By the late Sir James Frederic Goodhart, Bart., M.D., F.R.C.P. Twelfth edition, edited by George Frederic Still, M.A., M.D., F.R.C.P. London: J. and A. Churchill, 1925. (Demy 8vo, pp. xv + 995; 68 figures. 28s. net.)

and so, in its twelfth edition, is forty years old. Its unexhausted vitality is due especially to two things—to Goodhart's clinical genius, his power of himself seeing and imparting to others the essential clinical features of disease, and, secondly, to the wisdom and delicacy of Dr. Still's editorial pen, in piously preserving all that was good in the older editions and in skilfully grafting on to this stock the additions of modern knowledge. The book is too well known to require an extended notice (vide JOURNAL, 1921, vol. i, p. 934), and the present edition will carry on for a further period the life and service of a British medical classic.

The fourth edition of Dr. JULIUS HESS's book has as its title *Feeding and the Nutritional Disorders in Infancy and Childhood*.⁴ The third edition was entitled "Principles and Practice of Infant Feeding," but the scope and arrangement of the subject-matter remains practically unchanged, and the change of title only emphasizes the modern point of view in regarding the dyspepsias of infant life as disorders which affect, not only the digestive apparatus, but the whole system of nutrition. The inclusion of rickets, scurvy, and the anaemias of infancy under nutritional disorders is according to the classification adopted in the modern Continental textbooks on diseases of children.

The first three chapters are devoted to anatomy and physiology, and to breast and artificial feeding in the healthy infant. The next, on nutritional disorders in artificially fed infants, is the largest and most important in the book. The author mentions in the preface that "the classification, nomenclature, pathogenesis, and treatment of the nutritional disorders conform to the latest researches. American clinics are to be credited with the greater part of this progress." So far as classification and pathogenesis are concerned, the inspiration and foundation of this chapter are that of the German schools of Czerny and Keller and Finkelstein. The nomenclature is based on Finkelstein's grouping, and is given as follows: (1) nutritional disturbances unassociated with diarrhoea; (2) nutritional disturbances characterized by diarrhoea; (3) atrepsia; (4) anhydraemia. These are different words, but the ideas they denote are the same; they merely add to the already overloaded vocabulary of the subject. This chapter concludes with an account of coeliac disease. The remainder of the book deals with rickets, infantile tetany, scurvy, acidosis, and the anaemias of infancy.

The slim volume of x-ray pictures of the thorax in infancy,⁵ by Dr. ERICH SAUPE, forms the sixteenth section of Lehmann's atlas of medicine. It is based on abundant material of a special kind—more than a hundred cases where skiagrams of the thorax after death were followed by a *post-mortem* examination—as well as on numerous pictures obtained from the living subject. Twenty-seven photographs are reproduced, and, owing to their technical excellence and the glossy surface of paper used, make a useful if small collection of the common pathological conditions of the thorax in early life. But before the pictures are reached there is an introductory text of some sixty pages, in which, besides matters of technique, there is a systematic discussion of the various anatomical structures of the thorax and of the x-ray appearances of them in conditions of disease. It is in this introductory section that full details of the pictures reproduced are inserted, an account of the skiagram being followed by and compared with the morbid anatomy as revealed by dissection. This conjunction affords a novel and valuable control to x-ray appearances; but the method has not been fully worked by the author, who no doubt has been hampered by exigencies of space, although his material seems to be abundant. We have successively an account of some bone diseases and anomalies in ribs and vertebral column, of diaphragmatic hernia, of pathological conditions of the heart and great vessels, of the thymus and mediastinum, and of the lungs,

including bronchi, lung parenchyma, and pleurae. Many interesting points are raised and discussed, the failures and successes of x-rays in cases of enlarged thymus, the normal variations in the picture of healthy lungs, the visibility of the bronchi, and the very controversial questions as to hilus tuberculosis and the discovery of primary tuberculous foci. The author expresses very sensible and cautious views on the diagnosis of hilus tuberculosis from the presence of hilus shadows, and mentions a number of non-tuberculous conditions which give a similar picture. The section devoted to the x-ray photographs has certain defects which are rather negative than positive. The photographs are not numerous enough. For instance, there is not one of the normal thorax of the infant, and only one of rickets. Again, the descriptive paragraphs are too short, and the correlation of the morbid anatomy is not made clear. These, however, are faults for which the author is not entirely responsible, and which are remediable. He has more knowledge than he has presented, and many more photographs than he has been able to show. He has given an account of his subject which, if not complete, is interesting and well informed.

Professor HANS RIETSCHEL's book on children's diseases,⁶ which is the eighth of Lehmann's series of medical textbooks, is based on the atlas and outline of pediatrics by Professors R. Hecker and J. Trumpp. The book does not profess to be more than an introduction to the subject, and pays special attention to symptomatology and treatment. It is divided into two parts. The first or general part, consisting of forty-eight pages, is composed of four chapters devoted respectively to the anatomy and physiology of the child, physical examination, general treatment of sick children, and infant feeding. In the second part, which forms the bulk of the work, the several diseases receive consideration. With a few exceptions, such as the absence of any allusion to the Dick test in scarlet fever or "the pink disease," the book is well up to date. The text is accompanied by numerous illustrations, seventy-five of which are in colour.

SYNOPSIS OF SURGERY.

Mr. HEX GROVES has subjected his well known *Synopsis of Surgery* to comprehensive revision for its seventh edition.⁷ Numerous skilfully planned pen-and-ink diagrams have been inserted, which add to the convenience and advantage with which the book may be used, and a chapter on surface markings has been added. Once the larger textbooks have been mastered this synopsis offers very valuable assistance to those whose time is limited, or whose memory requires refreshing. A rigid methodical arrangement is followed throughout; each subject is put in its proper place, the gist of each shortly and clearly stated, and anatomical and pathological facts are only introduced when they have a direct bearing on diagnosis and treatment. Very useful, too, are the short chapters on diagnosis. The section on fractures stands out among others as of particular excellence; it is well up to date. Operative procedure is only dealt with on broad principles, but recent operative methods, such as Rammstedt's, Albee's, Hibbs's, are described; Steindler's operation might have been included. Keen's point on page 332 seems to demand the attention of the printer. We can safely predict continued popularity for the book, which will be found useful alike by the practitioner and by the student reviewing his knowledge before examination.

THE PATHOLOGY OF TUMOURS.

The second edition of *The Pathology of Tumours*⁸ by Professor KITTLE, now of Cardiff, has appeared at an

⁴ *Kinderheilkunde*. Von Professor Dr. Hans Rietschel. Zweite völlig neu bearbeitete Auflage des Atlases u. Grundrisses der Kinderheilkunde. Munich: J. F. Lehmann. 1925. (Sup. roy. 8vo, pp. xi + 446; 37 plates, 75 coloured figures, 101 figures in the text. Paper cover, M.22; bound, M.24.)

⁵ *A Synopsis of Surgery*. By Ernest W. Hey Groves, M.S., M.D., B.Sc. Lond., F.R.C.S. Eng. Seventh edition. Bristol: J. Wright and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd. 1925. (Cr. 8vo, pp. vii + 671; 149 figures, 13 plates, 17s. 6d. net.)

⁶ *The Pathology of Tumours*. By E. H. Kittle, M.D., B.Sc. Lond. Second edition. London: H. K. Lewis and Co., Ltd. 1925. (Demy 8vo, pp. viii + 284; 159 figures, 4 plates. 12s. 6d. net.)

⁵ *Feeding and the Nutritional Disorders in Infancy and Childhood*. By Julius H. Hess, M.D. Fourth revised and enlarged edition. Philadelphia: F. A. Davis Company. 1925. (Demy 8vo, pp. xvi + 556; 45 figures, 450 dollars net.)

⁶ *Das Thoraxröntgenbild im frühesten Kindesalter*. Von Privatdozent Dr. Erich Saupe. Band 16, *Lehmann's Medizinische Atlanten*. München: J. F. Lehmann. 1925. (Post. 4to, pp. 62; 27 figures on 14 plates, 2 figures in the text. M.10.)

opportune moment. For nine years the first edition has provided an excellent account of this special branch of pathology to those who sought more information than is provided by standard textbooks of pathology, yet did not aspire to the laborious task of searching through scientific journals for greater detail. To preserve its utility this book needed a few additions, and an occasional alteration, so that it should reflect the more recent points of view on some subjects. Dr. Kettle has made these alterations and incorporated the new doctrines which have been expounded within the last few months.

Readers to whom the earlier work was familiar will be glad to know that the revision has been accomplished without upsetting the original very sensible arrangement of the book. As before, it is divided into three parts, which deal successively with the general biology of tumours and the general and special pathology of tumours. The illustrations were always valuable, and the 159 pictures now provided seem even better than before. Many of them have been very skilfully drawn, the majority presumably by Dr. Kettle himself. The book is excellently put together, and, by a judicious selection of type and correct spacing, the impression is preserved throughout that every effort has been made to consider the comfort of the reader.

NOTES ON BOOKS.

DR. OTTO NEUSTÄTTER'S monograph on *Max Pettenkofer*⁹ forms the seventh volume of the series of medical biographies edited by Professor MAX NEUBURGER. The volume deals with the multifarious activities of a man who was not only a remarkable chemist and physiologist but first and foremost the pioneer of practical hygiene in Germany. At an early stage of his career he came under the influence of Liebig at Giessen, who made him acquainted with the achievements of British workers in sanitary science. Pettenkofer was subsequently appointed first extraordinary and then ordinary professor of chemistry in the medical faculty of Munich, and in 1865 became the first occupant of a chair of hygiene, which he held until the time of his self-inflicted death in 1901. As we pointed out in our obituary notice of him (JOURNAL, February 23rd, 1901, p. 489), Pettenkofer was responsible for numerous sanitary reforms: the creation of a sanitary service, the institution of chairs of hygiene in Germany, and the erection of the Institute of Hygiene at Munich, of which he was appointed director in 1872. Dr. Neustätter gives a graphic account of the opposition Pettenkofer encountered as pioneer of a new department of medicine. He was even unable at first to get his papers published in the ordinary medical journals. Consequently in 1865, in conjunction with Buhl, Radlkofer, and Voit, he founded the *Zeitschrift für Biologie*, and eighteen years later the *Archiv für Hygiene* in collaboration with Hofmann and Förster. His success as a teacher, to which his attractive personality in no small degree contributed, was shown by the large number of distinguished hygienists, not only in Germany, but also in foreign countries, who, at one time or another, were his pupils. A bibliography of his works is appended.

In a Lyons thesis on inoculation against enteric fever and cholera¹⁰ Dr. LOUIS PONCET records the results of an inquiry as to the procedure adopted for the enforcement of this prophylactic measure in twenty-eight European countries. It appears that antityphoid inoculation is compulsory for certain classes and particularly for soldiers in ordinary circumstances, in war time or during an epidemic, in the following countries: Austria, Belgium, Bulgaria, Czecho-Slovakia, Finland, France, Germany, Greece, Italy, Jugo-Slavia, Latvia, Lithuania, Poland, Rumania, Spain, and the Union of the Soviet Republics. In Great Britain and Ireland, as is well known, antityphoid inoculation, without being compulsory, has been carried out on a large scale, especially in the Dominion forces and in the services generally during the great war. Except on rare occasions, it has never been compulsory in Albania, Danzig, Denmark, Esthonia, Holland, Norway, Portugal, Sweden, or Switzerland. Vaccination against cholera is rarely indicated in Europe, but it has been enforced temporarily in Austria, Greece, Italy, Jugo-Slavia, Poland, and Rumania, and in the French armies of the East and Levant from 1915 to 1924. Dr. Poncet's inquiry was

conducted by means of Esperanto, of which he is one of the leading exponents.

*Electro-therapy and Ionic Medication*¹¹ by Mr. H. H. U. CROSS, Ph.D., has been written to meet the needs of the general practitioner who is interested in this branch of treatment. The subject is considered from the technical aspect, and the author gives a detailed description of all the chief types of apparatus used to produce electric currents for medical purposes. The descriptions are practical and contain many useful hints about the precautions necessary to avoid injuring delicate apparatus, so that an accidental short-circuit apparatus will not result in electrocuting the patient. About a quarter of the volume is devoted to ionic medication, which is treated in considerable detail. The use of the high frequency current is described shortly. An account is given of some of the chief types of x-ray apparatus, and the volume concludes with a description of the methods devised at Erlangen for the destruction of malignant growths by exposure to x rays. The author has had extensive practical experience, and the book gives a very useful account of the technical problems of electrotherapy.

The object of Dr. ICHOK'S work on the social protection of health¹² is to give the intelligent French layman a comprehensive view of subjects of medico-social importance, such as family life, industry, housing, the food problem, epidemics and epidemics, mental diseases, voluntary intoxications, criminality, pauperism, life in town and country, climate, physical education, and the international co-operation and social activity of the medical practitioner. An extensive bibliography is appended.

PREPARATIONS AND APPLIANCES.

Prescription (Humanized) Glaxo.

MESSRS. GLAXO state that Prescription (Humanized) Glaxo has been prepared in response to a general demand for a modified dried milk, which on simple dilution will give a solution containing fats, carbohydrates, and proteins in the proportions present in human milk. The preparation has been made in accordance with high medical advice, and on dilution 1 in 8 provides a fluid containing lactose 6.9 per cent., milk fat 5.1 per cent., and protein 1.7 per cent.

Opinions regarding the optimum fluid for the bottle-feeding of infants are notoriously divergent; this divergence is due, of course, to the enormous variation in the digestive powers of infants. The Glaxo process of drying milk, however, effects a change in the colloidal state of caseinogen, so that the addition of digestive ferments results in the formation of a light flocculent precipitate instead of the hard compact curd formed from raw cow's milk. This change must improve greatly the digestibility of the casein.

Reports from London hospitals submitted by the makers show that the practical tests of Prescription (Humanized) Glaxo are satisfactory; that it does not cause vomiting, diarrhoea, or constipation; and that infants fed upon it gained in weight.

A satisfactory infants' food, apart from its general nutritive value, must also contain an adequate amount of certain essential mineral constituents (for example, iron, calcium, phosphorus) and an adequate vitamin supply. As the calf grows much more rapidly than the human baby, cow's milk contains a higher proportion of these essential mineral salts than human milk, and hence there is no great danger of their being deficient in bottle-feeding. Extensive researches on the vitamin content of Glaxo have been carried out in the Glaxo laboratories by Messrs. Jephcott and Bacharat. These investigations show that Glaxo contains as high a content of vitamins A and B as fresh milk of good quality, and almost as high a content of vitamin C. Glaxo is prepared by the roller process as opposed to the spray process of drying, and experiments in England, France, and America agree in showing that roller drying produces no measurable destruction of vitamins, whereas spray drying causes almost total destruction of vitamin C.*

Messrs. Glaxo advise, however, that Glaxo feeding should be supplemented with orange or lemon juice. This is, of course, a wise attitude, since this precaution is advisable even in infants fed on fresh cow's milk. Prescription (Humanized) Glaxo appears, therefore, to be prepared in accordance with the best knowledge available concerning the elementary principles of infant nutrition.

MEDICAL RESEARCH COUNCIL.

ANNUAL REPORT.

THE annual report of the Medical Research Council for the year 1924-25¹ follows the same plan as those of previous years. After a brief introduction, wherein the chief work of the last twelve months is reviewed, the report proper first gives an account of the work done at the National Institute for Medical Research in each separate department. The next section deals with the question of the determination of biological standards and the methods of biological assay and measurement, a subject in which the Council has always taken particular interest. The fourth section deals with experimental medicine and the research work of clinical units, and gives a brief account of different investigations which are being supported in various medical centres throughout the country. The fifth section, headed "Research schemes in specific subjects," is the portion of the report which will interest most readers. In the pages of this section, which occupies nearly half the volume, the different specific subjects which are being investigated under the auspices of the Council are mentioned in turn and an account given of their progress during the last year. By a series of cross-references the editor of the report has made it easy for the reader to turn from this section to earlier or later sections of the report for administrative details concerning the different localities where any particular piece of research is being conducted. We shall, in this summary, follow the same plan, and give the main substance of the information contained under the headings of the different subjects which have been studied during the past year. We must mention also that a sixth section deals with industrial medicine and industrial fatigue, a seventh mentions the travelling scholarships awarded during the year, and a final section, headed "Conclusion," records the retirement of certain members of the Council during the year and also contains some obituary references. There are three indexes—one of personal names, one of institutions, and one of scientific subjects.

Not a few of the researches for which the Council has made grants have already been noted at greater or less length in our columns during the year, either in connexion with special reports or otherwise, but the following summary will be convenient for reference.

PROBLEMS OF CHILD LIFE.

The factors contributing to dead births, premature births, and neo-natal births have been studied by a group of workers at the Royal Maternity Hospital, Glasgow, who found that in a series of over 500 infants examined neo-natal death was due to disease or malformation of the child in about 16 per cent., to the complications of labour in about 33 per cent., and to maternal disease in about 50 per cent. The same group of investigators at Glasgow have continued their studies of the toxæmias of pregnancy, on which subject a full report is nearing completion. The results indicate that in all forms of toxæmia in the second half of pregnancy there is a disturbance of both kidney and liver functions, but the variations within each clinical group are so great that biochemical analyses of the kind made have given little help for the prognosis for individuals. A similar investigation is being carried out in Edinburgh in which the values of different tests of liver and kidney function in diagnosis, prognosis, and treatment are being assessed. Numerous investigations are in progress with regard to metabolism of infants, rheumatism in children, and rickets and tetany, but these have not yet been brought to the stage of yielding conclusions.

HUMAN NUTRITION.

Vitamins.

Dr. S. S. Zilva's work on the chemical properties of the antiscorbutic vitamin has been carried a stage further by

Report of the Medical Research Council, 1924-1925. H.M. Stationery
154 pages. 3s. 6d. net.

the demonstration that the active principle obtained from a variety of sources can be fractionated by the same reagents as those found effective with lemon juice. Dr. Zilva's work recently had an important practical application, because he was asked to superintend the preparation of large quantities of lemon juice for the stores of the *Discovery* whaling expedition, using the previous knowledge he had gained of the stabilization of the antiscorbutic factor. This juice is being tested periodically, and the results will be compared with those of clinical observation made by Dr. Marshall, the medical officer of the expedition.

Work carried out by Dr. J. C. Drummond and others, at University College, shows that the active material in cod-liver oil is represented by not more than 10 per cent., and probably a good deal less, of the unsaponified fraction from the active oil. In other words, the quantity of active substance required to enable the young rat of approximately 100 grams in weight to grow is of the order of two millionths of a gram a day. Experiments with highly purified preparations of cholesterol showed that this substance acquires powerful antirachitic properties, and in some cases growth-promoting action, after comparatively short exposure to ultra-violet radiations. Dr. Rosenheim has devised a series of colour tests which it is hoped will form the basis of colorimetric methods for assaying vitamin A values: already it is possible to compare the value of a number of samples of cod-liver oil by this means in a few minutes, and to obtain a result at least as accurate as that given by animal-feeding tests requiring a month or six weeks. Miss E. M. Hume, working at the Lister Institute, carried out an interesting investigation to determine the vitamin A content of spinach which has been grown behind a screen of glass comparatively impervious to the ultra-violet rays of light, as compared with that of spinach grown in the open. There appears to be no difference in the vitamin A contents of the two kinds of spinach.

Proteins and the Kidney Functions.

Two years ago work was begun at St. Thomas's Hospital to ascertain what detrimental effect, if any, excessive protein diet exercised on renal function. Although medical writers are almost unanimous in declaring that high protein diet is harmful in kidney disease, yet there is little sound evidence that this is so. Preliminary experiments gave irregular results, and those hitherto published by others were not confirmed. Ultimately it was found that the albuminuria and other evidence of renal damage alleged by various investigators to result from high protein feeding apparently depended on lack of vitamins or some other essential constituent of fresh food. If a very small amount of cabbage be given to rabbits, no renal changes are produced, even when the animals are kept on an otherwise exclusively protein diet for long periods. There seems to be no evidence that excessive protein diet, as such, is harmful to the kidneys. The extreme sensitiveness of the renal system to lack of vitamins is very striking, and it is highly probable that attention to this point may be of importance in the general treatment of nephritis.

At St. Thomas's Hospital also some striking observations have been made of the effects on the chemical exchanges of the body, especially those affecting carbohydrates, produced by various disturbances of the ductless glands. It seems that many patients suffering from disturbances associated with obesity show various points in common with the diabetic patient who is receiving large amounts of insulin: indeed, it seems probable that some endocrine disorders are associated with the presence of an excess of insulin in the system.

DISORDERS OF THE CARDIO-VASCULAR SYSTEM.

In the cardiographic department of University College Hospital Medical School, Sir Thomas Lewis and his assistants have continued their researches into circulatory problems, and the report refers to several scientific papers which have been published during the year. Dr. Drury found that cold, pressure, and increased acidity all depress the rate of conduction in auricular muscle and, if sufficient

in degree, prevent the impulse from passing. In all these conditions the wave becomes slower as it progresses, and is eventually brought to a halt in the muscle. These conduction defects are not due, as previously supposed, to change in the length of the refractory period, but to a phenomenon akin to that which has been described as "decrement" in nerve. The researches open up a new field of observation so far as cardiac muscle is concerned, and an important new line of thought.

DISORDERS OF EXCRETORY SYSTEM.

Financial assistance has been provided for work on experimental nephritis at the University of Manchester by Professor J. S. Dunn and Dr. N. A. Lovett. During the year a study has been made of the influence of water diuresis on the urea retention of acute oxalate nephritis, and results have been obtained which point to copious elimination of urea by the renal glomeruli. Dr. S. L. Baker, receiving a part-time grant at the Middlesex Hospital, has studied two cases of obstruction of the renal tubules caused by the excretion of haemoglobin following the intravascular haemolysis of transfused blood. Experiments have been made to determine the conditions under which haemoglobin is excreted and is thrown out of solution *in vitro*. The results indicate that with the excretion of haemoglobin in the glomerular transudate, which, like the blood plasma, is slightly alkaline, renal obstruction is due to the increase of the acidity and salt concentration in the tubules, which causes precipitation of the pigment, probably in the form of haematin. This would explain the production of intrarenal obstruction in cases of the type described and also in blackwater fever. A suggestion for the treatment of these conditions is, accordingly, the production of an alkaline diuresis.

THE GLANDS OF INTERNAL SECRETION.

Professor V. Korenchewsky and Miss M. Carr have been working at the Lister Institute on the influence of the sexual and prostate glands upon the chemical processes of the body. They conclude that the sexual glands contain hormones which increase nitrogen metabolism, and that the varying effects upon the nitrogen metabolism actually obtained after injection of emulsions of testis or of ovaries may be explained: (1) by the presence in them of specific substances (for example, of the corpora lutea in ovaries) or of non-specific substances (for example, of insulin type) in varying amounts; (2) by various degrees of functional efficiency in the synergetic and antagonistic endocrine glands. The experiments suggest also that the prostate gland produces an internal secretion which has an effect on thyroid activity.

INSULIN AND DIABETES.

At the National Institute Dr. Burn and Mr. Marks have continued their work on the influence of the thyroid gland upon the response made to insulin. It appears that the thyroid hormone alters the balance normally held between output of sugar from the liver and its removal from circulation by accentuating the response of the liver, thereby increasing the hyperglycaemia produced by adrenaline and reducing the effect of insulin. Moreover, when the liver, owing to a persistent excess of response under prolonged administration of thyroid substance, has lost its reserve of glycogen, the animal acquires a secondary and extreme sensitiveness to insulin. This is shown, not only in the effects produced by injecting insulin itself, but also in those following the injection of glucose, the uncompensated response of the pancreas to this stimulus liberating sufficient insulin to remove all the available sugar from circulation, so that death from hypoglycaemia results. Many other investigations into insulin therapy are being assisted by grants from the Medical Research Council. The work of Dr. G. A. Clarke at Sheffield has already brought new knowledge on this question. He has shown that stimulation of the vagus produces a secretion of insulin. Repeated stimulation—for example, by pilo-

carpine—causes a temporary condition of diminished glucose tolerance, an effect which cannot be produced after section of the vagus.

TUBERCULOSIS.

Dr. Dudley and Dr. Laidlaw of the National Institute are investigating the chemical nature of a material prepared by Dr. Laidlaw from tubercle bacilli. This substance yields precipitates in extremely high dilutions with the serum of an animal immunized against the whole protein constituents of tubercle bacilli, but will not itself evoke the production of such a precipitating serum. Like a similar specific substance obtained from pneumococci, it has proved to be a complex carbohydrate, free from nitrogen, having the properties of a gum. On hydrolysis it yielded pentoses and a more complex nucleus which resisted disintegration. The identification of these bacillary constituents, formed apparently by the linkage of simple sugars, yet reacting with such exquisite specificity with the antibodies formed in an animal injected with the corresponding bacillary substances, opens a new and fascinating field in immunology. In a report published by the Tuberculin Committee in 1925 on tuberculin tests in cattle, with special reference to the intradermal test, it was shown that a modified intradermal test was the one most easily used and gave the most consistent results. The committee has continued to advise various authorities, associations, and private individuals on the tuberculin testing of cattle.

The treatment of tuberculosis by sanocrysin has been tested in several hospitals during the last year. Professor Moellgaard, courteously gave the Council a full supply both of the gold salt and of the protective serum for clinical trials in this country, and arranged that his preparation should not be made available for general use until the results of these trials were known. A preliminary report on these first clinical trials has been published. The evidence so far obtained justifies further study of this drug; all observers seem to agree that the gold salt has some action on tuberculous tissues, but Sir Almoth Wright concludes from his experiments that sanocrysin exerts no direct bactericidal effect upon the bacilli in human tuberculous lesions.

THE PNEUMOCOCCUS GROUP.

Dr. R. R. Armstrong's work on immunity against the pneumococcus has been assisted by a grant from the Council. He worked with a standard strain of pneumococcus Type II of constant virulence, and, using the protective power of the serum upon mice as the index of immunity, he has been able to plot curves of the onset and progress of the immunity produced in rabbits by a single or multiple doses of vaccine. The immunity shows itself, after a single adequate dose, in from three to five days, reaching its maximum in eight days. The process has been similarly studied in naturally occurring lobar pneumonia in man, and is found to follow an almost identical course. A comparison of the relative effects of raw and sensitized vaccine was made by similar methods, and it was found that while sensitized vaccine rapidly conveys a certain degree of passive immunity it is inferior to raw vaccine in its ultimate immunizing power. These results have an obvious and important bearing upon the application of vaccines in the prophylaxis and treatment of pneumococcal infections.

Dr. Gaskell, working at Cambridge, has continued his experimental work on the production of pneumonia. Further evidence has been obtained that the kind of damage produced in the lung depends upon the virulence of the infecting organism, and not upon the dosage of infection given, if the dose does not fall below an effective minimum. The chances of the introduction of an effective dose, which is probably brought about in human infection by the passage of small quantities of saliva down the trachea, are greatly increased with the increase of virulence of the infecting organism. On the other hand, the frequency of terminal bronchopneumonia produced by an organism of comparatively low virulence in conditions of prolonged unconsciousness, such as cerebral haemorrhage, can be explained by the comparatively gross inhalation of saliva that such conditions allow.

FILTER-PASSING VIRUSES.

Malignant Disease.

The Medical Research Council has always given every encouragement to research work on the filter-passing viruses. The researches of Dr. Gye and Mr. Barnard, which attracted so much attention last year, were carried out at the Council's Farm Laboratories, Mill Hill, and at the National Institute at Hampstead. The essential features of Dr. Gye's work were that he showed that the filterable virus of the Rous sarcoma could be shifted in fluids containing it by very rapid rotatory movement, and is therefore corpuscular. In the second place, he devised means of cultivating the organism artificially. He found evidence that the cultivated and isolated germ could not, when acting alone, produce a new tumour, but only in the presence of an equally essential second factor, a non-corpuscular and therefore a non-living and soluble chemical substance which could be obtained from the substance of the previous tumour. The ultra-microbe, together with the chemical factor, regularly gave a new malignant tumour. Mr. Barnard devised special means for demonstrating the presence of this microbe and for gaining some first approximation to its description by using ultra-violet light having wave-lengths shorter than those of visible light. With a view to gaining information more rapidly with regard to the possibilities lying within this work on cancer, and in view also of the assistance it may bring to the work upon canine distemper and other studies of filterable viruses, the Council is constructing additional laboratory accommodation at Mill Hill, to which Mr. Barnard's Department of Applied Optics, including the work upon ultra-filtration, will be moved from the National Institute at Hampstead.

Vaccinia and Variola.

Other filter-passing viruses also have been studied intensively during the period covered by this report. Dr. Mervyn Gordon's work on vaccinia and variola has been published during the year, and we called attention to it when it appeared; he also communicated an account of it to the Section of Pathology and Bacteriology at the Annual Meeting of the British Medical Association at Bath.¹ He gave reasons for the conclusion that the immunity reactions which the virus evokes are closely analogous in all respects to those elicited in similar conditions by the better known pathogenic bacteria. The virus of vaccinia was shown to be particulate though invisible by ordinary means: its virus can be thrown down from its clear suspension in fluid when it is exposed to specific agglutinating antiserum. Dr. Gordon showed also that in the absence of a wound the easiest mode of access to the animal body by the virus is through the lining membrane of the nose. This observation of the special susceptibility of the nasal mucous membrane may provide a useful link between the agent of vaccinia and the unknown causative agents of influenza and of common colds. Dr. Gordon found that the viruses of small-pox from five separate epidemics, when compared by strict serological methods, all gave positive reactions with antivaccinia serum. No difference in this respect could be found between the virus from the mild type of small-pox sometimes called *ala-trim* and that from the severe examples of the disease. Recent observations by Dr. Gordon indicate that the distribution of the cow-pox virus amongst animals is even wider than has been believed hitherto.

Encephalitis Lethargica and Herpes.

Further work has been done by Dr. J. R. Perdrau on encephalitis lethargica and herpetic infections. The main conclusions he has formed are that the virus of herpes is identical with the causal agent of encephalitis lethargica, and that the almost complete failure of workers to infect susceptible animals with the latter is probably due to the presence of an antibody in the infected brain tissue. These conclusions were tested during the year and were confirmed by the demonstration of the herpetic virus in the brain of the only fatal cases of encephalitis lethargica

available, three in number. An antibody formed in response to inoculations of the herpetic virus has been found to neutralize *in vitro* comparatively large doses of the virus.

EXPERIMENTAL EPIDEMIOLOGY.

The studies in experimental epidemiology, mentioned in previous reports, have been continued during the year, and are now under the joint direction of Professor W. W. C. Topley and Dr. M. Greenwood. In a first report on this work the data of experimental epidemics of pasteurellosis in mice, lasting for more than three years, are analysed and discussed. Definite and significant conclusions can be drawn from the observed results of the immigration of susceptible animals into an infected population. It is shown that pasteurellosis will continue as a fatal infectious disease within a herd of mice for an indefinite period, exceeding at least three and a quarter years, or more than a complete generation, speaking in terms of the normal lifetime of the mouse, on the sole condition that the population at risk is replenished by susceptible but non-infected animals. The mortality of such a population is not steady, but shows wave-like reinforcements. The death rate increases with increasing immigration, but not to such a degree that the deaths outnumber the additions. The intervals between the waves of mortality are longer when the rate of immigration is low; when the immigration rate is high those intervals become very short, and tend to become merged into a steady high level of mortality. It is obviously not true, so far at least as the animal and infective organisms studied are in question, that an infectious disease can be brought to a standstill in an infected community, even by rigorous exclusion of infected immigrants.

SPIROCHAETAL JAUNDICE.

Dr. George Buchanan has continued his work on spirochaetal jaundice, and examined 51 suspected cases occurring throughout Scotland. In 22 a positive clinical diagnosis was made and subsequently confirmed by laboratory findings. Of the 22 cases, 8 occurred among coal-miners, in addition to 9 earlier cases which had been diagnosed on clinical symptoms alone. Anti-spirochaetal serum was used in several cases, and had apparently effective results when given during the first week of illness. Dr. Buchanan is studying several questions which may throw light on the epidemiology of this disease. Several wild rats from Edinburgh and other parts of Scotland and samples of water from mines and elsewhere have been examined for the presence of *Leptospira icterohaemorrhagiae*. Pathogenic leptospiras were isolated from a high percentage of rats; organisms of the same genus were also found in many samples of water, but the proof of their pathogenic identity is not complete. The organisms passing from infected rats were found to lose their pathogenicity outside the body, and there is reason to believe that human infection from soil or water, fouled by infected rats, probably occurs only after quite recent contamination.

INDUSTRIAL INVESTIGATIONS IN WORKSHOPS AND FACTORIES.

The investigation of the effects of short rest pauses introduced into long spells of repetitive work has been continued by the staff of the Industrial Fatigue Research Board. Since the comparison made by Dr. H. M. Vernon and Mr. T. Bedford of the outputs in certain factories over periods respectively before and after the introduction of rest pauses, full facilities have been obtained in four factories for practical trials, with continuous observation of the workers. This part of the investigation has confirmed the previous work in showing that the judicious introduction of rest pauses almost always has a beneficial effect, and that the workers unconsciously respond in such a way that their output is increased notwithstanding the shorter time actually worked.

This concludes our review of the researches described in the report of the Medical Research Council. We shall deal with the question of biological standards in a separate article.

British Medical Journal.

SATURDAY, JANUARY 23RD, 1926.

THE SEQUELAE OF EPIDEMIC ENCEPHALITIS.

THE lecture on post-encephalitic Parkinsonism by Dr. Arthur J. Hall, which we publish this week (p. 127), not only suggests some useful lines of treatment, but serves to draw attention to the disastrous after-effects of epidemic encephalitis. The latter, indeed, constitute one of the most sinister features of the disease, and, as Dr. Hall points out, owing to the fact that disease of the nervous system and disorders of behaviour may follow a mild or unrecognized attack and may not develop for six, twelve, or eighteen months after the acute illness, or even, in rarer cases, not for years, it is difficult at present to estimate the actual incidence of this disease in the community or the extent to which it is followed by permanent organic damage. The disorders of behaviour, taking the form in some cases of definite delinquency, must be regarded as one of its most serious results; and more particularly is this true since, when associated with very slight or unrecognized neurological signs, the origin of the changes in personality may not be detected, and the patient may thus be inadequately or even unjustly dealt with.

The relation between lethargic encephalitis and delinquency has recently been brought to the notice of the public by Mr. Charles G. Ammon, M.P., who has written letters to the *Times* (January 6th and 16th) on the subject. The immediate occasion of his letters was the case of a youth of 20 who, at the age of 14, suffered from encephalitis which left him morally and mentally impaired. He was treated as an out-patient at the Maudsley Hospital, and later, owing to the development of suicidal tendencies, certified. Subsequently he was taken out of the mental hospital by his mother, under Section 79 of the Lunacy Act. Later the lad was sentenced to three months' imprisonment for stealing a bicycle, the magistrate being unaware of his previous history. On December 22nd, 1925, he was brought before the magistrate at the Lambeth police court charged with stealing a shilling; and, knowing that the mother had not apprised the magistrate on the earlier occasion of the medical history, Mr. Ammon acquainted him with the facts, with the result that the lad was eventually bound over and placed on probation for twelve months. That such a case opens up the whole problem of disease and delinquency Mr. Ammon recognizes, and he asks whether we are to add to the numbers of our criminal population in the days to come owing to inefficient methods of education and control, or whether we are to take the long view and be prepared to spend more money on special schools and medical and other methods, in order that the potential criminals, pathological rather than vicious, should be turned out as good citizens. In a contribution to the discussion on this subject in the *Times* (January 13th) Lord Henry Bentinck, chairman of the Howard League for Penal Reform, supports Mr. Ammon's views, but refers to the number of epileptics, cripples, and persons accused or convicted of attempted suicide who are found in the prisons, and expresses the hope that a special institution should be

opened for encephalitic cases, and that this should form part of a larger scheme for the provision of treatment for all pathological offenders.

We do not doubt that Mr. Ammon has done a considerable public service in writing about this particular case, and it is gratifying to observe how closely the views expressed by the various correspondents are in accord with those held by the medical profession in general and psychiatrists in particular. As we have indicated above, it is difficult to estimate the number of mental cases associated with lethargic encephalitis. Many in which the home care must be quite inadequate are uncertifiable under the Lunacy or Mental Deficiency Acts, and the medical practitioner and social worker are powerless to deal with them; like so many potential and pathological delinquents, nothing can be done till they commit some offence, and even then, as Lord Henry Bentinck points out in his letter, a medical report is often only the beginning of the magistrate's perplexities. In the last report of the Board of Control it was stated that its register showed that there were 140 patients suffering from the after-effects of the disease in mental hospitals, and about 60 in mental deficiency institutions. Forty-three of the patients in mental hospitals are under the age of 20, and for them it is particularly desired to find some other form of accommodation. It is considered that the study and treatment of this new condition can be more effectively secured by collecting the patients into institutions under the observation of a medical staff in close touch with a centre of medical education and research. With this end in view the Board approached the authorities of London and Lancashire with the suggestion that the patients scattered in the institutions of these respective counties should be transferred to one mental hospital and one mental deficiency institution in each county where special facilities for research existed or could be developed. Each of these authorities responded as regards both its own mental hospital and mentally defective patients, but they were unable to adopt the suggestion to make provision for out-county patients of this type. The Metropolitan Asylums Board has made special provision, however, for patients with encephalitis lethargica as well as for those exhibiting its after-effects. Negotiations are also in progress, the report states, between the Board of Control and the committee of the County and City of Oxford Mental Hospital, with the object of securing an additional centre for concentration of cases at that institution.

In a recent paper¹ dealing with the psychological aspects of lethargic encephalitis Dr. G. A. Auden, school medical officer for Birmingham, gives a vivid description of the abnormalities of behaviour which develop in many children who have suffered from this disorder. The chief mental disturbances are a reduction of intelligence, marked irritability, character changes and moral defects, perverted habits, and disturbances of sleep rhythm. It is not, as he observes, the sleepiness by day which is the most distressing feature of the last symptom, but the noisy irresponsibility at night, which destroys the whole household's rest, and this in the often overcrowded homes from which many of the children come is a curse to the overburdened parents. Dr. Auden suggests that in the theory of the evolution of the nervous system put forward by Head and Rivers we may find the key to a proper understanding of the volitional defects and character changes of encephalitis. On the one hand, there is a reduction of epicritic control; on

¹ Encephalitis Lethargica—Psychological Implications, *Journ. Ment. Sci.*, vol. LXI, p. 647.

the other, a tendency to the obliteration of the distinction between *meum* and *tuum*, the all-or-none type of irritability, complete disregard of the interests of others (manifested in the nocturnal orgies of singing and shouting), together with the failure of self-criticism, which seem characteristic of a protopathic condition. In such cases, as Dr. Auden observes, punishment can have little or no deterrent effect, but, on the contrary, may have disastrous results by fixing an antisocial attitude. Furthermore, the conditions under which many of these children live render treatment at home both ineffective and for other reasons undesirable. Most medical men who have had experience of these cases would agree with Dr. Auden that institutions for their reception are one of the most urgent needs of the present time. It is thus satisfactory to know that the Ministry of Health, the Board of Control, and many local authorities are making every endeavour to provide care for these cases in institutions where they can be properly classified, re-educated, and provided with adequate outlets in the form of occupation and recreation. Apart from the pressing need of care, control, and treatment of these post-encephalitic cases, investigations in relation to the sequelae of lethargic encephalitis may be expected to shed considerable light on the problems of psychiatry, for here the changes in temperament, character, and instinct are clearly associated with demonstrable biological changes and disease of the nervous system.

Thus from the social aspect we observe in the encephalitic symptom-complex a significant relationship between delinquency and disease, and from the pathological aspect a problem which requires the full resources of psychiatry, neurology, and general medicine for its solution.

THE PRODUCTS OF CINCHONA IN THE TREATMENT OF MALARIA.

The Institute for Medical Research, Federated Malay States, has issued as one of its *Bulletins* (No. 3 of 1925) some further notes of great importance relative to the use of "cinchona febrifuge" and the alkaloids of cinchona in the treatment of malaria. The research, which was carried out by Dr. William Fletcher, was directed to finding answers to two problems which confronted the Malay Government: first, the advisability of employing cinchona febrifuge to supplement quinine; secondly, the policy of planting cinchona in Malaya. The causes that have led to the need for considering these problems and a scientific solution of them are detailed in this report, which is both informative and well written.

The term "cinchona febrifuge" has a different significance, at the present day from what it had originally, fifty years ago. In 1874 it meant a mixture of the active principles extracted from cinchona bark; now it is the residue after removal of quinine—in other words, any mixture of the by-products of quinine manufacture which the makers choose to put upon the market. Since the action of bark in malaria is due to the crystallizable alkaloids contained—quinine, quinidine, cinchonine, and cinchonidine—the value of the "febrifuge" depends on the amount of these remaining. Its composition is, therefore, not constant, and it contains amorphous alkaloids, classed together as "quinoidine," which cause toxic symptoms, vomiting, and diarrhoea. The four crystalline alkaloids have been proved to be equally serviceable in a dose of 10 grains twice daily;

in smaller quantities quinine and quinidine are superior. The booming of quinine to the exclusion of the other alkaloids has led to the restriction of cultivation of cinchona to the yellow varieties, which give a larger yield of quinine, and these can be grown only in certain places, such as Bolivia and Java. The red bark contains about half the proportion of quinine, but does not need special soil and climate. There is no real shortage of quinine, as has been stated, but the drug is expensive owing to the cost of production and restriction of output.

At Kuala Lumpur two groups of men suffering from various forms of malaria were treated, the one with quinine, the other with cinchona febrifuge. The former drug proved quite satisfactory in doses of 0.1 grain per kilo twice daily; by doubling the dose equally good results were obtained with the febrifuge. Larger doses of the latter were not necessary, and, moreover, caused toxic symptoms owing to the contained amorphous alkaloids, which are valueless as regards malaria. Cinchona febrifuge is, therefore, to be looked upon as an inexpensive method of treating the disease, but owing to the varying composition and the length of time required for making a difficult analysis for legal control, it is proposed that the Government of the Malay States should purchase the production in bulk, have it assayed, put up in tablets, and issued authoritatively. It could thus be used of standard composition for the majority of the people, while quinine could still be employed by those able to afford it.

The next investigation recorded by Dr. Fletcher is a comparison of quinine with quinidine sulphate. Seventy-two patients were divided into two groups, and were given twice daily 0.1 grain per kilo body weight of the respective drugs. The results are reported in detail, but may be summed up by saying that the immediate effect of the quinidine salt on the temperature and disappearance of the parasites was slightly better than that of quinine. Previous reports on the value of cinchonine had been contradictory; the discordant results are believed to be due to impurities in some of the samples used. As in the previous investigations, the patients were divided into two groups: one received 0.1 grain per kilo body weight twice a day, the other double this dose. In comparison with quinine the smaller quantity proved less effective in reducing the fever and clearing the peripheral blood of parasites; the larger doses, however, were as effective as quinine, and the alkaloid was not more toxic.

The upshot of this work is, therefore, to show that quinine need not be kept at the high price which it fetches at present; that there is no real world shortage of quinine; that in the other, neglected, alkaloids we have quite efficient substitutes; lastly, that from the red barks, which can be grown much more easily than the yellow, products are obtainable perfectly efficacious for the treatment of malaria inexpensively.

THE COLONIAL MEDICAL SERVICES.

THE controversy between the British Medical Association and the Colonial Office in connexion with the application of the new Regulations for the East African Medical Service (referred to in a leading article in the *BRITISH MEDICAL JOURNAL* of January 9th, 1926, p. 59) has given rise to a considerable amount of comment in the lay press. Unfortunately, in several instances the exact point at issue has not been made clear, and in general the notes which have appeared would seem to have been inspired by the

views of the Colonial Office rather than by any close examination of the Association's statement printed in the SUPPLEMENT of January 9th. In particular, there appeared in the *Times* of January 14th, under the heading "Medical Service in East Africa: Action by the B.M.A.," a statement which seemed to the Executive Subcommittee of the Dominions Committee, which met that afternoon, to be so misleading as to require a detailed rejoinder. A special statement was accordingly drawn up and forwarded to the *Times*. This appeared in the *Times* of January 18th, with an editorial introduction explaining that the former article represented the views of the Colonial Office—an explanation quite sufficient to account for the terms of that article. An exception to the general statement that the lay press has given priority to the views of the Colonial Office is afforded by *East Africa*, a weekly journal devoted to the interests of East and Central Africa, which reprints in full in its issue of January 14th the statement published in the SUPPLEMENT of January 9th. A note from Nairobi in the same journal deals with the opposition of the elected members of the Kenya Legislative Council to the formation of a unified East African Medical Service, and confirms reports already received from the Kenya Branch of the British Medical Association. Apparently there is considerable feeling in the colony that this is a step towards the federation of the East African Dependencies, and as such constitutes a breach of an understanding that no such step should be taken without consultation with the European section of the community. With this aspect of the controversy the Association has, of course, no concern, except in so far as it involves the general principle that no policy should be enforced at the cost of a breach of faith. It will be unfortunate if any valid obstacle to the unification of the service should emerge at this stage in the development of East Africa, for the measure is clearly conducive to a more efficient provision for the public health. In the SUPPLEMENT this week (p. 27) is reproduced the correspondence between the British Medical Association and the Colonial Office.

DIPHTHERIA CONTROL IN AUSTRALIA.

An intensive campaign against diphtheria was conducted at Bendigo, Victoria, during the years 1923 and 1924, and the story of this effort is reported in a publication of the Health Department of the Commonwealth of Australia (Service Publication No. 28). During the year 1923 more than 7,000 children were examined by swabbing the nose and throat, and 9.69 per cent. were found to be "carriers." The average age of these carriers was 8.7 years. The percentage of carriers was found to be much higher in the congested urban districts than in the rural, and in the great majority of carriers some pathological condition was present in the child's nose or throat. Virulence tests showed that 42.5 per cent. of the carriers harboured virulent diphtheria bacilli. The next phase of the campaign was the application of the Schick test to the school children in this district. In order to secure parental consent articles were written for the local press and meetings of schoolmasters were addressed by medical officers. Among 5,761 children the consent of the parents for the application of the Schick test was obtained in 1,616. About 46 per cent. of these children gave a positive reaction; among 147 carriers the percentage was approximately the same—namely, 43. The third stage of the campaign was the immunization of susceptible children by inoculation with toxin-antitoxin mixture. The serum was prepared by the Commonwealth Serum Laboratories, and three doses were given of 1/8, 1/2, and 1 c.cm. Consent was obtained for the immunization of 673 of the 725 children who gave a Schick positive reaction, but for various reasons it was not possible to complete the course of injections for all. Schick tests were

carried out again two months after treatment, and in most cases it was found that the treatment had abolished the previous positive reaction or considerably reduced its strength. It is too soon to expect the efforts made to combat diphtheria to show any very dramatic change in the case incidence in the district, but it appears that fewer notifications are now being received, and for the last three weeks of the month of August, 1924, the diphtheria ward of the Bendigo Hospital was empty, for the first time in the history of the hospital. Dr. Keith Moore, the author of the report, observes in his review of what has been achieved that the residual diphtheria in this district may be due to the fact that the campaign did not effectively reach the age group of 2 to 5 years—that is, the pre-school population—among whom diphtheria reaches a high incidence. Also, the Schick testing and active immunization reached only 40 per cent. of the total school population, or 25 per cent. of the total child population of the district. It is unlikely that in such an area as this Schick testing and active immunization alone will provide an abrupt conclusive solution of the diphtheria problem. Dr. Moore wisely concludes that the established methods, based on notification of cases and activities indicated by the circumstances of the actual known case, should not yet be discarded or modified in any detail. Such measures secure a following up of every case and the careful swabbing of every contact or possible contact, combined with a perfecting of early diagnosis and segregation, and the education of doctors as well as parents in dealing with all cases of slight throat ailments.

RESEARCH IN MENTAL DISEASE.

In his annual report for the year ending November 30th, 1924, Dr. C. Macfie Campbell, the director of the Boston Psychopathic Hospital, has taken occasion to plead for a broader conception of the nature of research in mental disease. Research is not to be looked upon as an activity of absolutely different nature from that involved in the regular tasks of the wards and of the laboratories. Research, he says, depends more upon an inquiring spirit than upon unusual facilities. The research worker was not made from different clay from his fellows, and the busy house officer or laboratory worker, if of a sensitive and inquiring turn of mind, would derive from his daily experience material worth digesting. There were few patients admitted in whom an intelligent house officer did not see the possibility of obtaining data which would have some bearing upon at least one of the many unsolved problems of psychiatry. The data might refer to the problem of the constitution of the individual; to the influence of early experiences on later personality; to the causation of symptoms by environmental stress and strain; to the relationship between mental disorders and the simple bodily systems; to the part played in adult behaviour by subconscious factors; to the kinship of the mechanisms of mental disorders and those at the basis of important social phenomena such as delinquency or class embitment; to the influence of various modes of treatment, whether physical therapy, drug therapy, or psychotherapy. The study and treatment of a case could never be well carried on if it was looked on as possessing no research interest, and such medical work could only be properly done by a physician well informed of the present limitations of knowledge in regard to these topics, and eager to make some contribution to the solution of unsolved problems. Good medical care of patients and interest in research should go together. A considerable section of the report is concerned with the consideration of cases which have been referred to the hospital from the courts and other social agencies, and with the problems arising therefrom. There was much current misconception as to the attitude of the

psychiatrist towards court cases. At the Boston Psychopathic Hospital a steady stream of patients were referred by the courts, presenting problems of the greatest variety, in regard to which a psychiatric opinion was required. The extent to which such an opinion determined the disposal of the case varied considerably. In some cases the problem was seen to be almost entirely medical; in others there might be no convincing evidence of any pathological mechanism in the case, which therefore might have to be disposed of by the court in the accustomed legal way. The fact that the physician was specially interested in the individual, and studied him from the point of view of treatment, did not mean that the physician had a deterministic standpoint in regard to social behaviour, nor that his bias was in the direction of reducing the responsibility of the patient. Numerous illustrative cases are quoted in the report.

MEDICAL REGISTRATION IN THE IRISH FREE STATE.

ACCORDING to the Dublin correspondent of the *Times*, the Free State Government has announced this week that it proposes to introduce legislation in the Dail next month to extend for a further period of six months the present arrangement with the General Medical Council as to medical registration. It will be recalled that on February 23rd, 1925, a measure sanctioning the continuance of the Council's powers for a year from that date was enacted by the Free State Legislature. The Act provided that in Southern Ireland the Council's constitution and powers, and the powers and responsibilities of its universities and corporations, should continue to be regulated by the Medical Acts in the same manner as before the Irish Free State was established. On August 15th, however, the Executive Council of the Free State Government announced that it had decided to set up a separate *Medical Register* for the Irish Free State. That unexpected and most unwelcome decision immediately aroused the opposition of the medical profession, whose objections received widespread support in the daily press of Southern Ireland. The general opinion was that a serious error of policy had been committed by the Executive Council. Medical meetings of protest were held before the end of the summer in Dublin and elsewhere, and the situation was described in the *BRITISH MEDICAL JOURNAL* of August 22nd (p. 358), August 29th (p. 386), and September 5th, 1925 (p. 455). We can well believe that the Free State Government's latest decision to renew the 1925 Act for a further period after its expiry next month has been received with pleasure by all classes. With good will on both sides this should provide time in which to devise some satisfactory permanent arrangement. Meanwhile, and for six months from February 23rd, the General Medical Council continues to exercise authority in respect of registered medical practitioners in the Irish Free State, who for their part retain the professional rights and privileges they enjoyed before the State came into existence.

THE CHARACTER OF CLAUDIUS.

WE have recently received an interesting dissertation by Dr. Thomas DeCoursey Ruth, entitled *The Problem of Claudius: Some Aspects of a Character Study*, which was submitted some years ago to the Board of University Studies of the Johns Hopkins University in accordance with the requirements of the degree of Doctor of Philosophy, and has now been published. The author points out that, with the rise of scientific method in scholarship, a very fair

The Problem of Claudius: Some Aspects of a Character Study.
By Thomas DeCoursey Ruth. Baltimore: The Lord Baltimore Press
(2nd ed., 1925.)

Julius Caesar and Augustus, and even of Caligula and Nero, has been gained during the last century, but that the characters of Tiberius and Claudius, particularly the latter, remain perplexing problems. This research, it appears, was not undertaken merely to elucidate the character of Claudius, but also with the intention of laying due stress upon his mental and physical peculiarities, with the object of arriving at a proper estimate of their nature and extent and of their influence upon his personality and reputation. The study of his behaviour and physical defects as presented by ancient authorities leads Dr. Ruth to the view that Claudius was neither imbecile nor insane, but that he was the subject of infantile diplegia, or Little's disease. As a result of this physical disability Claudius was subjected to severe stresses, indignities, and hardships in childhood, and it would appear highly probable, as the author believes, that the abnormalities of behaviour which the emperor exhibited in his later years might have been largely due to the effect of these traumata acting on a sensitive disposition. The writer is not a physician, but he submitted the clinical data obtained from his research to competent medical men, and his diagnosis has been well thought out. It is evident that modern psychiatry and neurology are capable of shedding much light on the characters of historical personages, and this dissertation will no doubt have an interest and value for both the general and the medical historian.

ANTIMALARIAL TACTICS.

THE report of the Malaria Advisory Board of the Federated Malay States for 1924, short though it is, affords abundant evidence that the authorities are fully alive to the dangers of any relaxation of effort in the campaign against mosquitos and against those responsible for allowing them to breed unchecked. Particulars are given of legislative measures suggested, debated, and carried during the year. They aim at fixing upon the individuals or bodies at fault the responsibility for permitting remediable insanitary conditions to remain. This is effected by regarding such conditions—among them, for example, such as tend to favour the propagation of mosquitos—as actual or potential dangers to the public health, and therefore penal as statutory nuisances. When there is any doubt as to the party responsible the board meets to discuss the question—a most satisfactory mode of deciding differences of opinion which inevitably crop up in nearly all colonies between the health department and the public works officials. Paris green as a larvicide has been well tested, and it is interesting to note that it proved excellent as a destroyer of the larvae of both anophelines and culicines, but was without effect on eggs or pupae. A special investigation is in progress relative to the important problem of malaria and rice cultivation. Finally, propaganda work is being energetically pursued by means of demonstrations, lectures, and pamphlets in English, Malay, and Chinese, whereby all races and classes may be reached.

HELMINTHS AND HEALTH STANDARDS.

FOR a long time the literature of tropical medicine has been inundated with reports upon hookworm infections and the dire evils which these parasites cause, either directly or indirectly. Hardly a single symptom can be named which has not been attributed at some time or other to ankylostomiasis. It is therefore a matter for congratulation that the problem is now being tackled from a common-sense point of view. Dr. R. M. Gordon has investigated without bias the effects on the general health, physical standard, the mentality, and the energy of West African natives of the three commonest and most widely distributed

helminthic parasites.¹ It is true that the inquiry dealt with a comparatively small number of individuals, but the results proved most interesting and instructive. He divided the patients into groups and devised three standards of efficiency, which he has designated A, B, and C. An illustration appended to the paper shows, so far at least as a photograph can, that the physical standard of the comparatively heavily infected may be equal to that of the lightly infected. The effects on the haemoglobin percentage were too variable to allow reliable deductions to be drawn, but it was found that a certain group of heavily infected individuals actually gave a higher reading than others less severely attacked. Mental alertness is a difficult matter to assess, but heavy infections on the whole had a deleterious influence in that none of those affected attained the standard of Group A. A similar lowering of the standard of energy, gauged by the "keenness with which an individual attempts any mental or physical task allotted to him," was demonstrated in those harbouring large numbers of worms. For preventive purposes, to obviate spread of infection to others, treatment of cases is the correct procedure, but, in the author's opinion, a medical practitioner in the tropics is not justified in undertaking mass treatment without first examining as to the degree of infection and the pathogenic effects of hookworm on the race among whom his lot is cast. Dr. Gordon's contribution may be the start of the backward swing of the pendulum, but we must be careful not to argue too readily, on the basis of a few cases, from the particular to the general when so much evidence has been adduced to the contrary.

A CONDEMNATION OF APÉRITIFS.

In France grave concern is expressed, both by public bodies and in the medical profession, at the recrudescence of alcoholism. At the end of September last year the General Council of the Department of the Rhône passed a resolution, which was supported by M. Herriot, the President of the Chamber of Deputies, demanding prohibition of the aniseed liquors which are sold under a variety of fancy names. The Council regarded these liquors as substitutes for absinthe, the consumption of which was prohibited by statute in 1922; and the reason given for the resolution was the increase of insanity, which was stated to be in direct relation with the increase in the consumption of alcohol. The subject of the recrudescence of alcoholism was raised at the Académie de Médecine on three occasions last year. In July Professor Achard called attention to the renewed abuse of wine and spirits, and the evils of alcoholism it was bringing with it. In November M. Jean Lépine, professor of nervous and mental diseases at Lyons, stated that nervous and cerebral affections had, for some time past, taken on a special character, which he attributed definitely to the abuse of alcohol. In December M. Cazeneuve read a communication² attributing the recrudescence particularly to the abuse of aniseed "apéritifs." M. Cazeneuve disclaimed any intention of advocating a "dry" régime. In fact, he agreed with Bouchardat that "wine is the most important of fermented drinks, the most useful when employed with discretion, the least harmful, in certain respects, even when abused." It was the essence of anise, which had toxic properties like all the essential oils, that led to the dangers of the abuse of apéritifs, especially of the absinthe substitutes; and the decree of 1922 in banning absinthe had the grave objection of giving, as it were, official recognition to the consumption of the principal flavouring element of absinthe, the essences of

anise and star anise. M. Cazeneuve admitted that essence of anise, and its active principle anethol, did not rank high in the scale of toxicity among aromatic substances. But all essences were objectionable in daily use; and in apéritifs they led insidiously to alcoholism. Notwithstanding the protests of manufacturers of apéritifs, the reports of alienists and of Professor Richet had shown the harmfulness and dangers of these beverages. M. Cazeneuve concluded his address by inviting the Académie de Médecine to pass a resolution to the effect that more rigorous control should be exercised with regard to absinthe substitutes; that the terms of the decree of 1922 concerning absinthe substitutes should be reconsidered with a view to reducing their toxicity; and that an educative campaign should be opened for combating abuse in the consumption of alcoholic beverages. The resolution was not adopted, but in accordance with the Académie's custom M. Cazeneuve's communication was remitted to the committee on alcoholism. It is not quite clear whether M. Cazeneuve attaches more importance to the toxicity of essence of anise or to the excess in alcohol to which the flavour lends inducement. But it would appear that in France the taste of aniseed, which in this country is usually associated with paregoric and cough mixtures, has a peculiar attraction; and that the Frenchman, deprived of his pet flavour in absinthe, has taken to the consumption of substitutes in which the alcoholic element is potent. So far as England is concerned it does not seem necessary to condemn entirely the occasional use of cocktails and apéritifs—such, for example, as vermouth, which in our issue of August 29th last we described as standing, when compared with absinthe, much as a light wine to a spirit. Nevertheless, the habitual use of toxic essential oils which excite the cerebral cortex is to be deprecated; and where, as appears to be the case in France, they lead to alcoholic excess, restrictive measures may be necessary.

THE HEALTH ORGANIZATION OF THE LEAGUE OF NATIONS.

In connexion with the sixth anniversary of the foundation of the League of Nations, which fell on January 10th, it may be worth while to mention some of the work done by its Health Organization, which now includes the United States, Germany, and Russia. The Organization has extended its activities to Africa, Asia, and America through the development of its Epidemiological Intelligence Service, its interchanges of medical officers of health, special inquiries into different diseases, and applied research work on serums, serological tests, and biological products. An International Conference on Sleeping Sickness, held in London, decided to send an international mission to Uganda to study the best methods of stamping out sleeping sickness in equatorial Africa; this mission is now on its way to the scene of its labours. The Singapore Bureau of Epidemiological Intelligence has been at work for some months, and its usefulness has been recognized by a request recently received from the French Government for the establishment of a similar bureau on the West Coast of Africa. At the Sixth Assembly (September, 1925) no fewer than seven Governments presented requests of one kind or another to the Health Organization. The League's work on the opium problem culminated at the beginning of the year in two international conferences—one dealing with the smoking of opium in the Far East, and the other more especially with the international supervision and control of the traffic in morphine, cocaine, and other dangerous drugs of addiction. A commission of inquiry will shortly proceed to Persia to study the possibility of assisting the Persian Government to reduce opium production by substituting alternative crops in the place of the opium poppy.

NINETY-FOURTH ANNUAL MEETING of the British Medical Association, NOTTINGHAM, 1926.

THE ninety-fourth Annual Meeting of the British Medical Association will be held at Nottingham this summer under the presidency of Mr. R. G. Hogarth, C.B.E., F.R.C.S., senior surgeon to the Nottingham General Hospital, who will deliver his address to the Association on the evening of Tuesday, July 20th. The Annual Representative Meeting, for the transaction of medico-political business and discussion of the internal affairs of the Association, will open on the previous Friday, July 16th. The sectional meetings for scientific and clinical work will be held on Wednesday, Thursday, and Friday, July 21st, 22nd, and 23rd. The names of the officers of the thirteen Sections are published in this week's SUPPLEMENT, and details of the arrangements for the Annual Meeting will appear from time to time in later issues. On the last day of the meeting (Saturday, July 24th) there will be excursions to places of interest in the neighbourhood. We publish below the second of a series of articles on the past history and present activities of Nottingham; the first appeared in the JOURNAL of December 5th, 1925 (p. 1081).

NOTTINGHAM: A BRIEF OUTLINE OF ITS HISTORY.

BY
E. L. GUILFORD, M.A.

WHEN history became a science it lost much of its charm. Many of the most delightful stories have had to be cast aside and the history book of to-day knows them no more. Yet there are few of us who do not cling longingly to some dearly loved personage who, we are told, never existed. Many of our oldest and best friends have thus to be laid up in the lumber room, and it is no longer quite respectable for us to acknowledge their acquaintance.

Modern historians tell us that nothing definite is known about Nottingham until the year 868. Perhaps they are right, but we can see the ghosts of earlier days lingering in the background, looking at us with sad, appealing eyes. What tales John Rous, Leland, and the rest had to tell us. Why should not Nottingham have been founded by King Ethelric in 980 B.C.? Why should not Lucius have founded it about the time when Troy was suffering from the persistence of the Greeks? Lucius's father was named Coilus, and he was our old friend King Cole of the nursery rhyme. Then we have the Wise Men of Gotham, whose senseless actions have been the delight of endless ages. Are they to pass away too? Robin Hood clings tightly to his footing in popular favour, and it will take more than a few dry-as-dust facts to make us deny his existence. Sherwood Forest still breathes his spirit of reckless yet chivalrous rascality, and long may it continue to do so. The Romans had several stations in this district, though between Lincoln and Leicester there was no place of first-rate importance. Exploration of some of these sites has taken

place, but so far little has resulted except from Margidunum, where results of great importance are being achieved. The Anglo-Saxons came, and soon all traces of Roman Britain passed away, and the villages we know to-day came

into existence, many of them taking their names from the leaders of the parties who settled down there. Nottingham and Newark certainly existed then, even if they had not done so earlier. Both these places occupy important positions guarding the crossings of the Trent by old main roads, and would have been occupied in strength from very early times. The Saxons bowed the knee to the virile Dane, and Nottingham entered upon a period when dates first begin to embellish its family tree. It is a curious period, full of war and destruction, murder and sudden death, and at the end this town emerges with a population composed of the different elements that had lived there. Angle and Dane have mingled and a very virile type evolved.

Then came the Norman—another hybrid, in whom the Dane predominated though the Frank persisted—and all England owned a new master. Nottingham grew rapidly. The feudal stronghold gave that reality of safety which the merchant had never experienced before, and the town, nestling beneath its wooden claimed, and won; hard cash was paid for charters, fairs were established, monasteries founded. The Norman brought a sense of security and orderliness which England had never known before. The reign of the weakling

OLD BRIDESMITH GATE, NOTTINGHAM.
(From a lithograph by M. Enfield.)

Stephen was a rude awakening to the possibilities of unlicensed feudalism, and Nottingham was laid low and its inhabitants experienced all the horrors of civil war. Henry II brought peace, and since then Nottingham has never looked back.

Notwithstanding the statements of many writers, it seems fairly certain that William Peverel built the first castle on the rock to the order of William the Conqueror. It was

only a wooden tower defended by a moat and a wooden palisading. As the art of offensive warfare advanced so the art of defence improved, and no doubt improvements were made at Nottingham which were viewed each in its turn as the last word. It was Henry II who first began to build a stone castle, spending enormous sums of money on this stronghold of the Midlands. Nottingham can hardly be called a barrier against the Scots, but it was a barrier against the North, and the North was always restless and full of potential danger. John, in his turn, made many improvements in what seems to have been his favourite home. It was so near to Sherwood Forest, and there he could find plenty to distract his attention from the cares of State, and in the chase no doubt he forgot the things it was unpleasant to remember. No one has succeeded in whitewashing John. He was too unpleasant a person for that ever to be successful, and certainly his death at Newark was a fitting one. At the head of an army of foreign mercenaries he had ravaged the wealthy districts of East Anglia, and then watched all his plunder sink beneath the quicksands of the Wash—and with them any hopes he had of recovering his position in England. Resting for the night at Swineshead Abbey, he overate himself and was forced to break his journey at Newark Castle, where, worn out by his follies, he died.

With the reign of Henry III Nottingham seemed to begin her career as a commercial town, as distinguished from a town that depended on the neighbouring castle for its life's breath. By steps she secured privileges which led eventually in the reign of Edward I to the concession of a mayor to look after the town. Nottingham's geographical position was making itself felt. Here at Trent Bridge was the highest point to which sea-going vessels could sail up the river, and so the wharves became very busy. The lead of Derbyshire, the timber of Sherwood Forest, the stone of the district, were all shipped here. When the fame of Chellaston alabaster spread even to the Continent, the great blocks were brought down the river and carved in the workshops

of the Nottingham "kervers." Coal, too, was early mined on the borders of Nottinghamshire and Derbyshire, and brought down for shipping to those parts which wanted this modern but smelly substitute for the more usual charcoal. There must have been a very considerable trade done in the charcoal burned in Sherwood Forest by methods which have been employed by man from the dawn of civilization.

The Great Market Place at Nottingham still stands as

it has stood for a thousand years, but now much more orderly than it used to be. The old wall that divided it from east to west, so that each of the two boroughs—the English and the French—might have its share, has disappeared; the horsepond with its ducking-stool, the sawpit, the pillory, and the stocks, are no more. The Malt Cross, the Butter Cross, are but names. In fact, much of Nottingham's past is written in its street names. We can

tell where the bridlesmiths worked, where the smithies were, where was done the work for which the smiths of the town were famous. Fletcher Gate shows us where the butchers, or flesh-hewers, lived; Pilcher Gate where the workshops of the furriers were to be found. Wheeler Gate used to be called Wheelwright Gate, and, earlier still, Baxter Gate—the resort of the bakers. Beastmarket Hill, Poultry, and Cheapside remind us of the different classes of goods that filled this great open space.

Unlike many mediæval towns, Nottingham had little to do with the Church. Beyond an occasional quarrel with its neighbour, the Prior of Lenton, it had none of the difficulties which towns owned by great ecclesiastics had to face. It was a royal town, and proud of it, but Newark was a perquisite of the Bishops of Lincoln and developed under their patronage.

History is dumb about many of the things we should most like to know. During the long wars with Scotland there must have been many a day of excitement for the peaceful burghers when some great lord or other, perhaps even the King himself, passed through, or spent a night at the castle. Then would the best the town could provide be called for, and (we hope) sent willingly. On the

other side we can picture the processions of wounded and prisoners—the latter treated according to their financial possibilities.

There is a great charm about the mediæval, and yet few of us would like to go back to those times: narrow, airless streets into which the filth and garbage of the houses were cast to rot, or, if luck served, to be blown away by a friendly wind. Can we wonder at the pestilences that decimated the country when we remember that, for many,

OLD TRENT BRIDGE, NOTTINGHAM.
(From a water-colour by C. MacArthur.)

CASTLE GATEWAY, NOTTINGHAM, CIRCA 1800.

the rivers were the drinking water, and into the river the sewage found its way?

When we come to the time of the Tudors we seem to breathe a purer air. Nottingham had been Yorkist in sympathy during the Wars of the Roses, but, like a wise commercial town, it had shed a silent tear for the death of Richard III, and hastened to congratulate Henry VII. Singularly little is known about the town under the Tudors. That it prospered and grew is evident, but it played little part in the nation's story. At the time of the Pilgrimage of Grace Nottingham for a time came faintly into the limelight. The Government was badly scared by the rising—in fact, it was frightened to a degree out of all proportion to the extent of the revolt. Nottingham, Newark, and the Trent were looked upon as a rear line of defence, and the Earl of Shrewsbury was very busy making preparations to meet an enemy who never came. Queen Elizabeth had practically nothing to do with Nottingham; in fact, Wollaton Hall was one of her visits, and a certain fame it is one of the great houses in which Elizabeth did not spend a night.

James I must have seemed very much of an anticlimax after Elizabeth. He passed through Newark on his way south in 1603, and hanged a thief without trial, much to the horror of law-abiding Englishmen. His son Charles was destined to be closely connected with the county. The troubles with Parliament were eagerly discussed, and the bulk of the people were not strong supporters of either side, so that when Charles I eventually raised his standard outside Nottingham Castle in 1642 he met with a rather chilly reception, and left for Shrewsbury in disgust. With his departure began the struggle between Parliamentarian Nottingham and Royalist Newark with its numerous outposts in the great houses of the county. It is a thrilling period to read in detail. Gradually Parliament and then the Army gained the upper hand, until only Newark remained to Charles. He himself escaped out of beleaguered Oxford and made his way via Stamford to Southwell in disguise and then surrendered to the Scots' commander outside Newark. It was a picturesque ending to a dramatic career. After Charles had paid for his inconsistency and instability with his life, and Cromwell was finding the problem of what beyond his considerable powers, what remained of it—was destroyed, and no doubt served as a stone quarry to the town for many years.

James II brought trouble here as he did in so many places. His ideas were not in keeping with those of the majority of the citizens, and it was only by cancelling its charters that Nottingham was compelled to receive his nominees. Princess Anne and her friend, the famous Sarah Churchill, took refuge at Nottingham Castle—now rebuilt—when her father fled to France. When the Jacobite troubles came to worry George I and George II Nottingham was found to contain some supporters of the Stuarts. The excitement was considerable in 1745 when Prince Charlie reached Derby with his Highland army, and the fate of England was believed to hang on his decision to march south or north. Like all other troubles, it passed away, and gradually we can see the approach of the Industrial Revolution, which changed the face of England as with a magician's wand. Most of the great inventions in the textile industry, which have made England so great a figure in the commercial world, were connected in one way or another with Nottingham. The town reaped the benefit of its excellent geographical position with the coming of canals and railways. Trade flowed into and through the town, and soon Nottingham was famous for its lace and hosiery factories and its coal mines.

It had long been realized that the old bounds of the town were far too narrow; yet the common lands lay just outside the town, and the burgesses were reluctant to abandon their old rights. However, Enclosure Acts were brought to bear on the problem, and Nottingham overhauled rapidly, and soon, where once had been open fields, appeared streets of houses leading to the villages which had grown up on the far side of the common fields. Thus gradually modern Nottingham has come into being. All the work is not yet done, and there are still many improve-

ments to be made. The streets are being widened, the River Trent is being made deeper, so that Nottingham may once more become a great inland port. Nottingham has this advantage over many towns, that it has in the Great Market Place a central point from which to radiate in all directions.

Such, then, in brief is the story of Nottingham. It has a glorious past, and we, its citizens, believe that it will have a future no less glorious.

The illustrations accompanying this article are reproduced from photographs taken by A. Lincker, Nottingham.

THE CANCER INQUIRY OF THE LEAGUE OF NATIONS.

THE Health Organization of the League of Nations has recently published two volumes¹ describing certain studies of a particular problem of cancer. The origin of the inquiry was the remarkable difference between the rates of mortality from cancer of the female breast and from cancer of the uterus in certain European countries. England and Wales, Holland, and Italy were selected for special study, on the following grounds. In all three the official mortality data reach a high standard of accuracy, and very few deaths are recorded without medical verification. Two of the countries (England and Wales and Holland) suffer from a high death rate from all forms of cancer together; the third (Italy) has a relatively low death rate from cancer. But England and Wales contrasts with both the others in having much higher rates of mortality from cancer of the breast and uterus. Holland suffers from a compensating evil in her high rate of mortality from cancer of the stomach, etc. In Italy there is no such compensating disadvantage. Italy, however, has at most ages a higher rate of mortality than Holland (but a much lower rate than England and Wales) from cancer of the uterus. The contrast, therefore, with England held both in a country with and a country without compensation from another form of cancer, while, for one of the special sites, the country of lowest general cancer mortality did not have the least special site rate. The problem proposed was to explain these differences.

The Health Organization appointed to control the inquiry a very strong committee, presided over by Sir George Buchanan, Senior Medical Officer of the English Ministry of Health, and having as other members Professor Léon Bernard, of the Faculty of Medicine, Paris; Dr. H. Carrière, Director of the Swiss Federal Health Department; Dr. Josephus Jitta, president of the Health Council of the Netherlands; and Dr. Alberto Luttrario, formerly Director-General of the Health Department of the Italian Ministry of the Interior. Dr. Ewald Tomanek, of the League's Health Section, was secretary of the committee. So far the work done has been largely statistical, and its actual conduct has been entrusted to a special subcommittee, termed the Subcommittee of Statisticians, of which Dr. Major Greenwood (London) was appointed chairman and Professor Methorst (the Hague), Professor Niceforo (Naples), and Dr. Tomanek (Geneva) were the original members, but to which Professor Doelman (Groningen), Dr. Janet Lane-Clayton (London), and Professor Pittard (Geneva) have since been added.

The volumes now published are essentially the conclusions of this subcommittee, together with extremely detailed protocols of the evidence upon which the conclusions are based. It certainly cannot be said that the various members of the subcommittee have succumbed to the temptation, supposed to be especially severe in international inquiries, to furnish more eloquence than information. Thus Dr. Greenwood's *étude* on cancer of the breast and uterus in England and Wales occupies seventy-three foolscap pages, three of which are letterpress, the remainder tabular data and statistical constants; and his colleagues Professor Methorst and Professor Niceforo have been almost as sparing of words and generous in providing statistics.

¹ League of Nations Health Organization, Committee on Cancer, Vol. I, Report on the Cancer Mortality in Certain Selected Countries, Vol. II, Report on the Cancer Mortality in Certain Selected Countries, relating to Differences of Cancer Mortality in Certain Selected Countries.

The conclusions drawn by the subcommittee from this immense mass of data are set out under nine heads. Before referring to some of these, mindful of Queen Elizabeth and the citizens of Tilbury, we must say that the subcommittee has admittedly *not* found a satisfactory explanation of the striking differences which formed the starting-point of the inquiry. It has conclusively proved that the demographical peculiarities—variations of marriage rate, age at marriage, number of children to a marriage, etc.—which any medical statistician would say *a priori* might help to explain the differences, cannot do so. The subcommittee thinks it unlikely that any differences in certification or tabulation can go far towards explaining the facts. It has also—but to this we shall refer again—provisionally concluded that earlier or more frequent resort to surgical treatment cannot explain the superior position of Holland and Italy. All these are negative conclusions. The positive conclusions, if not a step towards the solution of the problem originally proposed, are still of importance. In the first place, the subcommittee is satisfied that child-bearing does not, with an exception to be noted, predispose the woman to cancer of breast or uterus. The subcommittee says:

"The impression has long prevailed that cancer of the breast and fertility were negatively associated. This has been based upon the general observation of the higher rates of mortality amongst unmarried women. It is fully confirmed by the concordant results of the analyses made by the method of correlation, using various indices of fertility. Evidence submitted to the subcommittee from the clinical side, namely, data of the fertility of married women suffering from cancer of the breast and statistics of the fertility of women taken as *controls*, who had not suffered from cancer of the breast, confirms the opinion that, when a comparison is instituted between women equally exposed to risk of pregnancy, those who develop cancer are less fertile. This material is necessarily very slender in comparison with official statistical data, but is at least a useful confirmation, since official statistics do not provide data so tabulated. Passing to the question of cancer of the uterus, the analyses are again concordant in showing that there is no positive, but, on the other hand, a negative relation between cancer of the uterus and indices of fertility. . . . The official statistics, therefore, are in accord with the opinions based upon clinical statistics of Professor Deelman and Professor Peller, namely, that the higher incidence of cancer of the uterus upon married women is a consequence of the immediate effects of a single parturition, and that women who have borne many children are less, rather than more, liable to cancer of the uterus in comparison with married women who have borne few children."

The subcommittee went into the question of the differences of rates of mortality within each country, and concluded that these differences far exceeded anything reasonably assignable to "chance." It concluded that "statistical indices, whether of race, extent of industrial employment or habits of life, sufficiently precise to be utilized for analytical purposes" could not be derived from any published or unpublished material at the disposal of official statisticians, and that if this subject were to be pursued special local sampling inquiries must be made. This suggestion has already been taken up.

The subcommittee calls attention to the rough uniformity of increase of the rate of mortality from cancer of the breast (married and widowed women) in England and Wales up to the age of 65, and notes that in the Netherlands there is hardly any increase with age after the group 60-70, and very little in Italy. "The subcommittee has devoted considerable attention to this phenomenon, and suggests that the possible influence of varying resort to surgical treatment in the three countries should be carefully considered from the clinical statistical point of view."

The subcommittee calls special attention to evidence collected by the late Dr. Eichel and extended by Dr. Boudreau and Dr. Tomanek, tending to show that in the United States of America there is a difference between the rates of mortality from cancer of the children of the nationals of the three countries similar to that found in the statistics of the countries of origin. The subcommittee presses for a continuance of this inquiry.

The second volume issued contains a report by the subcommittee on certain clinical statistics, followed by three preliminary notes by Sir George Buchanan on clinical inquiries in England and Wales, by Dr. Jitta and Professor Deelman on inquiries in Holland, and by Dr. Lutrario on the position in Italy.

As all the conclusions drawn in this volume are provisional, and the definitive reports of the clinical investi-

gations are likely to be published in the near future, we do not propose to say more than that the subcommittee records that "in each of the three countries one-third at least of the women suffering from cancer of the breast die without radical treatment." The subcommittee desires further "to point out that the results of the inquiry justify the statement that in each of the three countries a large number of persons die every year who, even in the present position of medical knowledge, might have lived considerably longer." The work of the League's Cancer Committee is, of course, still far from completion, and it would be premature to express anything but an interim judgement upon it.

We think the committee—or perhaps we should say the subcommittee—has carried out a valuable piece of work and set an example of patient and minute inquiry which ought to raise the general standard of medico-statistical work on cancer throughout the world. But we do not think that these publications will have much *direct* influence. As we hinted above, the contributors have been conscious that they were members of a subcommittee of experts and have refrained from any popularization of their reports; the reports are written by statistical experts for statistical experts.

It may be that at the present stage of the inquiry it is not expedient to make an appeal to the large number of medical readers who are deeply interested in the problems of cancer, but not even faintly interested in the question whether the local distribution of mortality from cancer of the breast does or does not follow "the rule of normal, Bernoullian, dispersion or any other theoretical schema."

Yet there are indications, especially in the report of Professor Niceforo (a comparison of Professor Niceforo's report with those of the other experts will enable the reader to appreciate the force of the remark that we have to-day two languages—*le français, et le français de la Société des nations*), that the experts could, between them, prepare a report which the mere doctor would be pleased to read. We hope they will take this hint, for there are many results in this report which, however familiar to experts, are probably quite unfamiliar to most medical men.

This at least any reader can deduce from the reports: that the members of the cancer committee and subcommittee live laborious days and do not regard Geneva as a centre for "joy rides."

England and Wales.

NEWCASTLE: DINNER TO SIR ROBERT BOLAM.

THE Newcastle-on-Tyne Division of the British Medical Association held a reception at the College of Medicine on the afternoon of January 13th. There was a large attendance of members and their wives, and of the final-year students, who received a special invitation. Dr. J. Maxwell Gover, Chairman of the Division, and Mrs. Gover, and Sir Robert Bolam, Chairman of Council, and Lady Bolam, received the guests, and Dr. G. C. Anderson, Deputy Medical Secretary, was present. The function, which was of the nature of a *thé dansant*, was a great success. Sir Robert Bolam received a special ovation from the students in view of the honour conferred on him at the New Year. On the same evening, at the Central Station Hotel, the Division entertained Sir Robert Bolam to dinner. It was singularly happy that the desire of the Division to honour him had taken form before it was known that his services to the profession were to be publicly recognized. The company numbered 150, and this included chairmen and secretaries of Divisions in the North of England Branch. In proposing the toast of "Our Guest," the Chairman (Dr. Gover) referred to the valuable work Sir Robert has done as Chairman of the Council of the British Medical Association, and especially to his successful efforts in connexion with the new headquarters of the Association in London. They were delighted, he said, that His Majesty the King had seen fit to recognize his services. A Newcastle man born and bred, and a graduate of Durham University, they were proud to honour Sir Robert. The toast was received with acclamation, and

Dr. Gover then handed to the guest of the evening a souvenir of the occasion in the form of a mezzotint of Sir Charles Hastings, the Founder of the British Medical Association. Sir Robert Bolam feelingly replied, and touched on various matters of medico-political and ethical interest. The toast of "The Headquarters Staff" was proposed by Mr. F. C. Pybus, senior representative of the Division, and replied to by Dr. G. C. Anderson, Deputy Medical Secretary, who paid a warm tribute from the headquarters staff to Sir Robert Bolam. During the evening Dr. F. J. Nattrass rendered several songs and there was orchestral music.

THE LATE DR. RICHARD CATON.

A memorial service was held on January 14th in Liverpool Cathedral as a tribute to the life and work of a citizen greatly beloved and a highly esteemed member of the medical profession. The Lord Mayor and representatives of the city council attended, and a large congregation included representatives of the university, the medical profession, and various institutions and organizations with which Dr. Richard Caton was closely identified. Archdeacon Howson gave a short address on the words "A man greatly beloved," and in sympathetic phrases showed how well the late Dr. Caton throughout his life had merited its application. His old-world courtesy, his zeal in the ministry of healing, and his humility justified the application to Dr. Caton of what had been said of another greatly beloved professor in a different line of science: "He made belief in goodness possible for other men." Mr. H. Goss-Custard, the cathedral organist, played Chopin's funeral march, and the whole service was rendered with dignity and grace. Of Dr. Caton it may truly be said: "*Multis ille bonis flebilis occidit.*"

THE NATIONALIZATION OF HOSPITALS.

At a meeting of the Incorporated Association of Hospital Officers on January 15th Mr. Somerville Hastings, M.S., F.R.C.S., gave an address on the nationalization of hospitals. Mr. Hastings said that he was second to none in recognizing the good work that the voluntary hospitals had done. Not only had they vastly helped the sick poor, but it was in their wards and laboratories that practically all the researches in preventive and curative medicine during the last hundred years had been carried on. The voluntary hospitals also furnished the best example of team work in science, though he regretted that it did not extend beyond the four walls of the individual hospital, and that each hospital was an isolated unit. He considered, however, that the voluntary hospitals could no longer meet the needs of the public. He accepted the estimate that two and a half hospital beds were needed for every thousand of the population of England and Wales. That meant 95,000 beds, of which the voluntary system provided only just over 50,000. The Voluntary Hospitals Commission had stated that at least 10,000 more beds were required, but Mr. Hastings thought this figure much too low. He admitted that the higher figure was not borne out by the waiting lists, but this was, he thought, because mostly the names of people needing admission were not put down on the waiting list unless their cases were urgent or there was some prospect of their admission within a reasonable time. The present deficiency of beds would, he believed, increase for several reasons, which he enumerated as follows: the growing urbanization of the people, which increased the liability to sickness and accident; poverty consequent upon unemployment and the steady drop in wages; the housing shortage, which meant that fewer people could be successfully nursed at home; the growing complexity of medical treatment, which made it impossible for increasing numbers of people to provide such treatment for themselves; and also the intensified interest in health, which made people more inclined to seek advice and treatment instead of struggling on in illness. Hospitals were already receiving subsidies from authorities and payments from patients. This last arrangement opened the doors of the hospitals to the middle class. He was glad to see all classes using the hospital, but under present conditions there was some danger of the exclusion of the poorer, for

whom the hospitals were founded; and he feared lest such a diversion should occur in the case of hospitals as in grammar schools and other educational foundations originally intended for the poor. Since the war heroic efforts had been made to save the sinking ship of voluntarism. Gambling lotteries had become a recognized means of hospital assistance; Treasury grants had been made, and now the Voluntary Hospitals Commission recommended that two millions of the taxpayers' money should be handed over for more beds. Workmen's contributions, he thought, were unjust in their incidence, and a universal tax would be fairer. What he wanted to see was a completely organized medical service throughout the country, with the hospital as its centre in each locality, from quite small hospitals in the villages up to county hospitals, to which serious cases could be transferred, and, in the universities and large cities, national hospitals where medical students could be trained and special research performed. The Poor Law infirmaries, with all taint of the Poor Law removed, should be turned into first-class State general hospitals. Some of the large country houses which were continually coming into the market might be purchased and turned into State convalescent homes. To the voluntary hospitals three possibilities might be presented: they might (1) remain as they were; (2) be taken over by the local authority; (3) receive State or municipal grants in return for proportionate representation on their governing bodies. He added that he had been accustomed to speak at meetings of working people in all parts of the country, and nothing in the Labour party programme had been received with more enthusiasm than the nationalization of hospitals. Mr. Hastings's views were supported by Mr. G. P. Blizard and Dr. Ethel Bentham, of the Labour party, and the case for voluntarism was stated by several hospital officers, including Mr. E. W. Morris, house governor of the London Hospital, who urged that the administration of the Poor Law and of National Insurance had not been so successful as to warrant great hopes for hospitals under State management. The State was too heavy-handed and inelastic to deal with such a personal matter as sickness, but the Government might help immensely by taking over the expensive work of research.

THE LIVERPOOL HEART HOSPITAL.

The Liverpool Heart Hospital, the latest addition to the special hospitals of the city, was opened by the Lord Mayor, Mr. F. C. Bowring, accompanied by the Lady Mayoress, Mrs. E. W. Hope, on January 11th. It is situated in Oxford Street, where a late Victorian mansion has been converted to meet its new purpose and the object in view. It will have accommodation for fifty indoor patients. The equipment is complete, and an electrocardiograph has been installed. An out-patient department is provided, and patients can be seen daily at 1 p.m. The honorary staff consists of Dr. I. Harris, honorary physician, and Dr. Andrew Crawford, honorary assistant physician. Professor J. Martin Beattie is honorary consultant in bacteriology, and Dr. Percival W. Leathart, honorary bacteriologist and laryngologist. The chairman announced that a consulting had been made financially, as the hospital was good start from debt. He said that such a hospital was opened from diseases of the heart demanded most intimate essential, a careful thought, and prolonged care. The knowledge, hospitals were full, and there was neither the time, general he the beds forthcoming, to treat such cases. nor we're referred to the death of Dr. Caton, who was Dr. Harris energetic supporter of the hospital from its very inception, and mentioned the pioneer work he had done in connexion with heart disease. Admitting that specialization might have its drawbacks, Dr. Harris expressed the view that it was inevitable; so greatly had the knowledge of disease advanced that it was impossible for a physician to become proficient in the whole field of internal medicine.

BRITISH EMPIRE CANCER CAMPAIGN.

At the quarterly meeting of the Grand Council of the British Empire Cancer Campaign on January 12th, under the presidency of Sir John Bland-Sutton, it was announced that the total grants and commitments made by the council

now exceeded £75,000. One grant of £100 had been made to Mr. E. Nevill Willmer of Manchester University, for work on tissue culture, and a grant of £500 had been given to the Westminster Hospital for a special scheme of cancer research. The lines of study carried on by Dr. J. C. Mottram under a grant from the campaign had been amended with the approval of the Scientific Advisory Committee, in order to associate his investigations with those of Dr. Gye and Mr. Barnard. Inaugural meetings had been held in Essex, Kent, and Hertfordshire, with a view to forming county committees in support of the campaign, and meetings were to be held at an early date in Hampshire, Sussex, and Middlesex. The Yorkshire council began its campaign on January 18th, when it was announced that £150,000 had been already collected; it is proposed to devote £75,000 to establish an advisory research centre in Leeds University. Eighteen district committees have been formed in the county, and Sheffield has already raised £5,000. Birmingham is similarly organizing an appeal to endow a cancer research centre in its University.

RICHMOND ROYAL HOSPITAL, SURREY.

A voluntary scheme has been organized in connexion with the Richmond Royal Hospital with a view to providing a substantial income and the possibility of further extension. The deputy-mayor of Richmond, Mr. Arthur Howitt, presided over the inaugural meeting on January 12th, and gave an account of the proposals. The hospital serves a population approaching 280,000, but receives subscriptions from only about 600 people. In its present state £11,000 a year is required for maintenance, and there is need of improving the existing buildings and extending them. It is hoped that a sufficient yearly income may be obtained to obviate the necessity for flag days and other forms of collecting money. Members of the Richmond Hospital Association undertake to contribute £1 a year, and associates 10s.; junior members, under 18 years of age, pay 5s. H.R.H. the Duke of York is the president of the appeal, and the Lord Chancellor (Viscount Cave) the honorary treasurer.

Ireland.

SCHOOL OF PHYSIC, TRINITY COLLEGE, DUBLIN.

THE hundredth anniversary of the opening of the School of Physic of Trinity College, Dublin, was observed on January 13th, when an address on the early history of the school was given by Dr. T. P. C. Kirkpatrick, Registrar of the Royal College of Physicians of Ireland.

Dr. Kirkpatrick said that the teaching of medicine in connexion with Trinity College was started in 1654, when Stearne founded the College of Physicians. The causes which led to the two institutions drifting apart were described at some length. The rupture threatened to destroy the school, but its life was saved by the appointment of George Cleghorn, and, later, of William Hartigan, who was in turn succeeded by James Macartney, the founder of the present School of Physic. Macartney was born in Armagh in 1770, and studied anatomy under Hartigan in the school of the College of Surgeons. Subsequently he went to London, and in 1800 obtained the diploma of the College of Surgeons of England. He was appointed lecturer in comparative anatomy in the school of St. Bartholomew's Hospital, where he won a reputation as a brilliant research worker and an attractive teacher. He returned to Ireland as surgeon to the Radnor Militia in 1811, and two years later was elected professor of anatomy and surgery in the School of Physic. His election produced a remarkable change in the school. He was an untiring worker, and his energy irradiated the entire school. In the first year his class numbered fifty-three students. In 1820 the number of students in the anatomy class reached three hundred and three, and it was quite impossible to find room for them in the old Anatomy House. Macartney frequently urged the board to provide further accommodation for the school; on November 27th, 1820, permission was granted to use No. 22 Trinity College for

the lectures, and the board directed that plans were to be prepared for building a new Anatomy House. The choice of a site was not an easy matter, but eventually it was decided that the building should be erected on the ground heretofore the bowling green, at the north-east corner of the College Park. The committee was probably influenced in its choice of a site by a desire to keep the school buildings as far as possible from the rest of the College, but in the light of subsequent events the choice was wise. Macartney objected to the site on account of dampness, and because of the damage students were likely to receive by passing through Park Street to enter the school. Park Street was the former name of Lincoln Place, and had a bad reputation as the home of undesirable persons. The foundation stone of the new buildings was laid on July 4th, 1823, and the work proceeded quickly, though not quite peaceably. In February, 1824, there was something in the nature of a riot when the journeymen carpenters in combination attacked the other workmen. Later, when Macartney was inspecting the building, he met the architect, and in plain terms told him what he thought of himself and of the buildings. Words led to blows, and the interview ended by Macartney breaking his umbrella on the architect. An action at law was threatened, but the Provost succeeded in making peace between the would-be litigants. In spite of all trouble the building was finished, and there, on November 1st, 1825, Macartney delivered his inaugural lecture, in the course of which he said: "The Board of Trinity College has bestowed a more valuable gift upon the community by building this house than if they had founded ten hospitals." Macartney maintained his supremacy as a teacher till the end. The average number of medical students who matriculated every year during the twenty-four years he was professor was just over eighty-four. The corresponding average for the first decade of the century was just over eighteen. Macartney seemed to have come to consider that he was the school, and that everything and everyone should give way to his wishes and convenience. This the board could not allow, and on July 15th, 1837, his resignation was accepted. Six years later he died at his house in Upper Merriem Street, Dublin.

The twenty years that followed his resignation were momentous in the history of British medicine. In 1858 was passed the Medical Act, which for the first time brought the education and practice of medical men in these countries under the central control of the General Medical Council. The College was fortunate in having at the time at the head of the Medical Faculty the great William Stokes, who held the post of Regius Professor of Physic from 1840 till his death in 1878. Robert James Graves, whose name was so closely linked with that of Stokes, was King's Professor of the Institutes of Medicine from 1827 to 1841, and was, perhaps, the greatest figure in Irish medicine. His clinical lectures won for the Dublin School of Medicine a world-wide reputation. Other notable teachers mentioned by Dr. Kirkpatrick were William Featherston-Haugh Montgomery, Robert William Smith, Robert Adams, Thomas Brady, and Robert Travers. Robert Law, who succeeded Graves as King's Professor of the Institutes, continued to discharge the duties of that office till 1873. In February, 1874, John Malet Purser was elected King's Professor; he at once decided to lecture, not on medicine, but on physiology, and, in addition, to give lectures on practical histology. These lectures became popular, and in 1879 the board authorized an expenditure of £2,700 for the building of a laboratory for histology and physiology. Here was started that splendid instruction in practical pathology which was given by Dr. Purser every year till 1895, when Alexander O'Sullivan was appointed lecturer in pathology, and the laboratory of pathology was built at the cost of £9,000. Dr. Purser continued as King's Professor of the Institutes till September, 1901, and in 1917 he was elected Regius Professor of Physic. To Professor Purser's energy and ability as a teacher was due in no small measure the success of the school in later years. "We rejoice," said the lecturer, amidst loud applause, "to think that he is still with us." Trinity College had in her Medical School a great heritage, and for that school there was a future more

brilliant than its past. In its long history of two hundred and fourteen years it had met and overcome difficulties which threatened its extinction. Should such difficulties arise in the future they would, Dr. Kirkpatrick was confident, be again overcome. Never before had it a more competent staff, and never was it under the guidance of a more wise and sympathetic Board of Trinity College.

Scotland.

THE COMPOSITION OF MILK.

AN important study on variations in the composition of milk has been made by Mr. J. S. Tocher, D.Sc., F.I.C., Lecturer in Statistics in the University of Aberdeen. It is founded on analyses he made of 676 samples of milk (each sample being the milk of one cow) from cows of various breeds throughout Scotland during the years 1921-22. The regulations governing the standard of milk fixed by the Board of Agriculture, prescribe that milk shall not be regarded as genuine if it contains less than 3 per cent. of milk fat or less than 8.5 per cent. of solids other than milk fat. It is pointed out that the Society of Public Analysts considered these limits reasonable, although it was in favour of a higher standard being set than 3 per cent. of butter fat. It was recognized, however, that genuine milk might contain less than 3 per cent. of butter fat and less than 8.5 per cent. of other solids. Under the existing procedure, where a retailer is taken into court because he has sold milk which does not come up to this specified standard, he has to satisfy the magistrate in every way that the milk he sold was milk just as it came from the cow, with no addition of water or skim milk, and no extraction of butter fat or other solids. It is generally conceded that the quality of milk supplied to the public varies greatly from day to day, according to seasons, and according to the selection of the cows, and the present investigation was undertaken with the purpose of showing the exact nature of these variations in the constituents of milk, and how these variations are related to one another. The study of the summarized results enables a dairyman to improve the quality of his milk supply, and at the same time provides him with the means of eliminating several of the factors which would cause milk of poor quality to be yielded by a herd of cows. The average proportion of butter fat found for the whole of the 676 cows was slightly over 4 per cent., while the average proportion of solids not fat was found to be about 8.75 per cent. The consumer, however, is not supplied from so large a group of cows as 676, and a common number constituting a herd from which the mixed milk is supplied is about 20. With respect to the milk from individual cows, the proportion of butter fat was found to vary from 1.7 to 7.5 per cent. As many as 12 cows out of any 100 give milk containing less than 3 per cent. of butter fat at all times. The range of variation in solids other than fat for individual cows was found to be from 6.9 to 10.6 per cent. As many as 24 cows out of any 100 were found to give milk containing less than 8.5 per cent. of solids other than fat. Out of the 676 samples, 111 were found to contain a proportion of solids other than fat between 8.25 and 8.5 per cent. Other constituents of milk which the writer of the monograph has studied are lactose, casein, albumin, and mineral matter, and, in addition to the foregoing characters such as amount of yield, specific gravity, freezing-point, refractive index, and acidity were also studied and their relationship to each other and to the chemical constituents determined. The rather surprising fact was discovered that the greater the yield of milk the greater was the percentage of lactose present; in other words, a good milking cow is also a good sugar producer, and vice versa. It is also shown that a high percentage of butter fat is accompanied as a rule by a high percentage of other solids, due largely to the proportion of casein present. A milk containing 5.8 per cent. of butter fat was usually associated with about 4 per cent. of casein, while 3.2 per

cent. of butter fat was associated with 1.6 per cent. of casein. The average yield of milk at one milking was found to be about 14 lb., and the average age of milking cows was approximately six years. The yield of milk was found between morning and evening milk, except that there appeared to be a slightly greater percentage of solids of butter fat and of solids other than fat was found to be somewhat greater in stall-fed cows than in cows at grass. Tocher records the help given him by various workers, especially in the laboratory of the Rowett Nutrition Research Institution at Aberdeen.

A NATIONAL PARK.

A gift which will add considerably to the amenity and health of Edinburgh has been made to the nation by the late Mr. W. R. Reid and Mrs. Reid by their bequest of Davidson's Castle. The castle and grounds are situated at miles from the centre of the city. The grounds, which extend to about 180 acres, stretch along the south shore of the Firth of Forth, are well wooded, and afford beautiful views. The castle, situated within the grounds, is in part an old building, dating from the early seventeenth century, with modern additions; it contains a remarkable collection of furniture, prints, and objects of art, for which it is intended to form a museum. Along with the gift of castle and park, a sum of £36,000 has been bequeathed for their maintenance. The library of the late owners has been separately bequeathed to the Scottish National Library. In addition to its natural beauties and amenities, the property has interesting historical associations. At one time it belonged to the family of Law of Lauriston, and here was born John Law of Lauriston, who, after an adventurous early life in London, went to France, where in 1720 he became comptroller-general of the national finances, erected a national bank, and afterwards planned the ill-fated Mississippi scheme. The gift will form an admirable addition to the numerous public parks in the possession of which Edinburgh is so fortunate.

GLASGOW ROYAL INFIRMARY.

The annual report of Glasgow Royal Infirmary shows that the ordinary expenditure for 1925 was £110,194, while the ordinary revenue was £85,189; there was thus a deficit for the year of £25,005, as against £24,710 in the previous year. The total number of patients treated in the institution during the year was 13,959, an increase of 1,210 on the previous year. In the out-patient department 51,954 patients attended, an increase of 3,261. It was reported that the managers had been considering the formation within the infirmary of a new biochemical department for the investigation of problems arising in connexion with special diseases, and towards this object they had already received sums amounting to £5,500. An area of ground extending to twenty-two acres has been presented to the infirmary by Mr. James Macfarlane, LL.D., chairman of the managers of the infirmary, and his brother, Mr. George W. Macfarlane, for the purpose of erecting a nursing home in connexion with the institution. The site is at Canniesburn, on the western side of the city, and commands a fine view of the Clyde valley and the Kilpatrick hills. The gift has been accepted by the managers of the infirmary.

FIFE MINERS' CONVALESCENT HOME.

At a meeting of the executive board of the Fife, Kinross, and Clackmannan Mineworkers' Association at Dunfermline, Mr. William Adamson, M.P., the general secretary, read a letter from Mr. Augustus Carlow, managing director of the Fife Coal Company, Ltd., stating that the company intends to establish a convalescent home for miners, to be known as the "Charles Carlow Home." For this purpose it is proposed to take Blair Castle, Culross, a handsome mansion standing in pleasant gardens and wooded policies on an eminence near the north shore of the Firth of Forth; it should prove a site admirably adapted for the purpose, and the board agreed unanimously to accept the offer.

Correspondence.

VACCINE TREATMENT OF THE COMMON COLD.

SIR,—We general practitioners are just now being requested by the parents of schoolboys to inoculate them against influenza and colds, and they are being instigated to this by letters from headmasters, who, in their turn, have the idea suggested to them by the school doctors. It is gratifying to know that the latter are at last alive to the use of protective inoculation against colds. Dr. Simey's recent communication (BRITISH MEDICAL JOURNAL, November 14th, 1925, p. 901) seems to have started the ball rolling. The object of this letter is to inquire whether it is not possible for the medical officers of our big schools, who have hundreds of boys under their care, to do a little team work in this matter. We do not know which vaccine formula is the best; we do not know how many inoculations are necessary, nor how long the protection lasts; nor have we any decided opinion at what period of the year they should be given. I have given these for very many years now; at the start I selected a "blunderbuss" formula, the one containing the greatest different varieties of germs I could find. I believe I am indebted to Sir Thomas Horder for instruction as to the dosage and intervals. My practice has been to give four doses in increasing amount—at intervals of fourteen days between the first two, and one month between the subsequent ones. The results have been varied—one patient tells me the protection lasts him eleven months; as against this, I have been told by a pathologist that it lasts only six weeks; of course, there are all gradations, from those whom the smallest dose starts off at once with a cold, to those who have apparently complete protection.

If the medical officers of schools would only arrange each one to pursue a particular plan and use each a different formula, then, by pooling their results, we might arrive at better methods than those we have at present. For myself I am getting suspicious that I give too small doses; but I know that in vaccine therapy the swing of the pendulum is in favour of smaller doses than formerly.

There is one other point: how often do we see our patients go down with colds in the early autumn, after their return from the summer holiday. Does not that suggest that the time to begin injections is in July and that they should be carried on into October? If it is true that eleven months' immunity can be obtained, the winter would thereby be covered; though I confess I should rather like one or two, to make certain, in the mid-winter season.

I suggest that Dr. Simey and his colleagues in the schools should think this matter out, and, having a large number of patients to deal with, obtain from them the accurate knowledge we so much desire in this matter.—I am, etc.,

London, N.W.3, Jan. 13th.

LEWIS G. GLOVER, M.D.

NASAL DOUCHING.

SIR,—It was with satisfaction that I read Dr. Coyne's letter in your issue of January 2nd (p. 37), in which he comments on the "wholesome and wholesale attack on the prevalent habit of nasal douching" and sniffing by the lay press.

The highly complicated structure of the interior of the nose is sufficient to explain the danger. The folds of the turbinates provide plenty of shelf room for the storing of germs which cannot possibly be removed by any douching. As to sniffing—that act drives the air up towards the roof, where the olfactory nerves are housed. Where there are dust and germ-laden discharges lying in the pathway of the currents they must be driven up there too, to bombard the openings of the various sinuses. When these openings become obstructed the air in the respective cavities is gradually absorbed, sucking in whatever may be lodged against the openings. The warmth, moisture, and seclusion in the cavities are just the properties of an incubator. The risk of setting up chronic suppuration is obvious.

When the nasal cavities need cleaning, which must necessarily be very frequent since every breath draws in a certain amount of foreign matter which it is their function

to catch before it gets down into the lungs, it can only be done scientifically by clearing the offending matter out into the open—the method which is used in dealing with the waste of every other organ. The waste of the nose is the most important of all to be handled promptly, since it consists of dead and dying organic animal cells exposed to the outside air, while at the same time also the process of incubation is going on of the entangled germs. Nature has supplied us with the means for getting rid of this waste by giving us the faculties for sneezing and blowing—faculties which we share with all other members of the animal classes which have nasal chambers on the same plan as ourselves. It is only the human species which does not make full use of these powers.

No organ can safely be douched which has its walls perforated with small holes leading into blind cavities; especially when there is no gravity drain to some of them. Years ago Politzer emphasized the risk of damaging the ears with the nasal douche. His counsel is not being followed to-day as it deserves to be. Many cases of deafness are not relieved till the nose is treated rationally and scientifically.—I am, etc.,

OCTAVIA LEWIN, M.B., B.S.Lond.

London, W., Jan. 8th.

"CLINICAL MATERIAL."

SIR,—The following record of cases now or just lately under my care in the medical wards of Westminster Hospital may be of general interest. My own beds in the male and female wards respectively number as a rule seven, occasionally nine. There has been no exclusion from the list given of cases of less interest, and the list is in no way made up of selected cases. At one and the same moment or following each other in direct rapid succession the cases have been as follows:

Males.

Palsy of lower face, palate, vocal cord, and pharynx on one side in a man aged 40, who had also acute nephritis; sudden total inability to swallow anything. Fed by tube; rapid recovery of paralyses.

Carcinoma of middle of oesophagus. Gastrectomy.

Diabetes mellitus with coma in a boy aged 6. Relief by insulin; treatment by graft of whole pancreas seven months ago and without further insulin.

Simple ulcer of greater curvature of stomach. Partial gastrectomy; cure.

Angina pectoris. Resection of left cervical sympathetic nerve; relief.

Trigeminal neuralgia. Gasserectomy; relief.

Sudden total unilateral blindness with papilloedema, due to chronic infection of maxillary antrum. Operation; relief.

Vascular symptoms and motor weakness in an upper extremity; postural obliteration of arterial pulsation; x rays show no abnormal bony rib. Operation pending for cartilaginous rib.

Tabs dorsalis with brisk knee- and ankle-jerks; diagnosis made on palsy of a third cranial nerve, ulnar nerve analgesia, abolition of bulbo-cavernosus reflexes, hypotonus; tests positive.

Gunshot wound of skull, 1917; gap in bone; epilepsy with onset, 1925; meningeal cyst depressing brain.

Uraemic coma. Relieved chiefly by cistern puncture.

Mitral stenosis; no blood infection; cerebral and renal emboli. Recovery.

Syphilis of ocular nuclei; persistent negative serum Wassermann reaction; positive tests in cerebro-spinal fluid.

Case superficially resembling general paralysis; symptoms due to angioma of cerebral cortex.

Actinomycosis in a boy of 16.

Traumatic pneumothorax without fractures in a boy of 6 run over by a car. Aspiration; recovery.

Inspiratory fixation of thorax and diaphragm, non-organic; inability to speak. Rapid cure.

Cerebral arachnoid cyst in a boy aged 15 from trauma at 4 months; epilepsy from date of trauma to 6 years; diagnosis polio-encephalitis; freedom from 6 to 15 years; recurrence. Operation; cure.

Partial blindness and stunted physical growth in a boy aged 16; x rays show three calcified (?) tuberculomata in brain.

Very extensive haemorrhage into thigh and leg from slight indirect violence; high blood pressure.

Facial hemi-spasm from old trauma. Alcohol injection into foramen; relief of spasm without palsy; temporary complete palsy of muscles of spinal accessory.

Gumma of skull base and middle fossa; cranial nerve palsies.

Females.

Meningo-vascular cerebral syphilis with unconsciousness; persistent negative serum Wassermann reaction; positive tests in cerebro-spinal fluid. Recovery.

Two cases of Raynaud's gangrene of digits. Affected fingers saved by Leriche's operation on brachial arteries.

Sudden portal ascites at 27; rapid compression obstruction of inferior vena cava; liver tolerance tests normal. Laparotomy showed cirrhosis of liver.

Tabes dorsalis with local syphilitic lesion causing aphasia for written speech.

Lymphatic leukaemia; very large spleen; a single palpable lymphatic gland.

Syringobulbia; palsy of tongue, palate, and vocal cord. Head-aches successfully treated by ventricular puncture.

Hysterical perpetuation, after every meal for two years, of post-anæsthetic vomiting (operation for anal fissure); laparotomy elsewhere for relief on four occasions. Symptoms cured at a sitting.

True vicarious menstruation from stomach for a year in a girl aged 16 who, save once, has not menstruated normally; uterine infantile; the bleeding is periodic and the blood does not clot.

Abscess of an upper lobe of lung following tonsillectomy and pneumonia a year ago. Cured by incision and drainage after prolonged treatment by artificial pneumothorax had failed to relieve.

Cerebellar affection of acute encephalitis; long-standing "cerebral vomiting" treated successfully by psychotherapy.

Disseminated sclerosis; diagnosis made on story of past visual failure (retrobulbar neuritis) and ready fatigue of one abdominal reflex.

Hæmatemesis, without other gastric features, as a symptom of tabes dorsalis in a woman with healthy knee-jerks and negative tests for syphilis.

Urgent dysphagia due to adhesive palsy of anterior wall of oesophagus in a woman with evidence of syphilis.

Diphtheritic neuritis affecting *inter alia* the small muscles of the hands.

Long-standing dyspepsia; gall stones.

The surgery of the great majority of the cases enumerated has been performed by my colleague Mr. Rock Carling. Treatment, surgical as well as medical, has been conducted throughout in the medical wards, and the patients have been, from start to finish, under the observation of the same "firm."—I am, etc.,

HILDRED CARLILL, M.D. Cantab.,
Physician and Lecturer, Westminster Hospital.

London, W.1

TREATMENT OF CARBON MONOXIDE POISONING.

SIR,—In the *BRITISH MEDICAL JOURNAL* of April 25th, 1925 (p. 812), Dr. Holmes suggested the use of venesection and blood transfusion in carbon monoxide poisoning, and Sir C. Gordon-Watson (December 5th, 1925, p. 1049), has described certain cases of alleged carbon monoxide poisoning in which this treatment was used with advantage. I would like to point out that Holmes's suggestion is by no means new, for in my *Textbook of Forensic Medicine* (p. 212) I had already drawn attention to the possible value of this procedure.

This line of treatment, however, can be considered only of subordinate importance, and artificial respiration with inhalation of oxygen, mixed with carbon dioxide, to stimulate the respiratory centre, must necessarily remain the primary course to adopt. The cases discussed by Sir C. Gordon-Watson do not appear to me to be cases of carbon monoxide poisoning at all.

In the first place, the men all made their own way out of the dug-out, and the severe symptoms came on later, whereas in carbon monoxide poisoning loss of muscular power would have supervened at once. Secondly, the dark, almost black, colour of the mucous membranes is never observed in carbon monoxide poisoning. Thirdly, the spectroscopic examination failed to reveal any carbon monoxide hæmoglobin. Finally, the colour of the blood, which is always a bright cherry red or pink in carbon monoxide poisoning, was stated to be dark, with a chocolate-coloured fluid, which separated out from it.

From the history of the cases it appears that there was some agent present in the blood other than carbon monoxide, and that the symptoms were certainly not due to carbon monoxide. What this toxic agent was cannot be ascertained with any degree of certainty, but there is a strong suggestion that it was one of the nitrobenzene derivatives produced by the explosion of the shell which destroyed the dug-out or the Mills bombs. These substances cause symptoms which coincide with those described by the medical officer, and by their combination with hæmoglobin form some as yet unknown pigment which produces the dark blue or black colour of the mucous membranes and slaty grey colour of the skin, which was noted in all these cases.—I am, etc.,

SYDNEY SMITH, M.D., D.P.H.,
Principal Medical-Legal Expert,
Egyptian Government.

December 16th, 1925.

ACUTE INTESTINAL OBSTRUCTION.

SIR,—We have had the surgeon's point of view and the general practitioner's, with a certain amount of feeling on both sides. Both have something to be said for them, but the truth, as usual, is somewhere between the two. During nearly three years as a resident at the London Hospital I only saw one abdomen opened for intestinal obstruction where operation was not proved necessary. In that case the surgeon—a very able man (no longer living)—was at fault, and the child died. Perhaps I was somewhat to blame, as I told him there was no obstruction! On the other side of the picture, my own eldest child, then aged 2½ years, had an intussusception which I diagnosed. I called in the general practitioner (also no longer living) who kindly attended my family, and for whose opinion I had a great respect, and he called it gastric influenza, and said he would come in the next day. Not being satisfied, I got a surgeon to see the child, and he agreed with me; he operated at once and found the intussusception and saved the child's life. I did not blame the general practitioner, but I am very grateful to the surgeon. When my third child got intestinal obstruction I called in a surgeon at once, and all went well.

The moral I draw is that the surgeon may occasionally be too keen to operate and the physician may be too slow, and the best procedure for the patient is to have a consultation at the earliest possible moment. If there is any doubt, have the patient watched by the surgeon unless the general practitioner can really give all his time to it, and the general practitioner can then be summoned if and when the surgeon feels sure an operation should be performed. The patient meanwhile is far better in a nursing home or hospital, so that there is no delay when the decision is made, and has not got to make a journey in a critical state. Finally, I disagree with the statement that a diagnosis of intestinal obstruction is difficult to anyone who sees much of it. The surgeon has this advantage over the general practitioner, who may meet it very rarely.—I am, etc.,

Reading, Jan. 11th.

LESLIE POWELL, M.B.

ALIEN IMMIGRATION INTO GREAT BRITAIN.

SIR,—In the *JOURNAL* of January 9th (p. 59) you publish a notice of the *Annals of Eugenics*, and finish your summary of Professor Pearson and Miss Moul's memoir on "The problem of alien immigration into Great Britain" by the statement that "It does not appear from the results communicated that the Jewish immigrants do contrast favourably with native Gentile children," and hence it is concluded that there is a strong case against unrestricted immigration.

As Professor Pearson and Miss Moul have done me the honour of referring at some length to a paper of mine on "Tuberculosis and the Jew," contributed to the *Tuberculosis Year Book* some years ago, I trust you will be good enough to grant me space to make a few remarks upon their most learned paper. The authors quote the figures I published of the incidence of and mortality from tuberculosis in Whitechapel, as taken from the records of the Whitechapel Tuberculosis Dispensary. From these figures it appears that, whilst there were nineteen Jewish patients to one Gentile patient attending the dispensary, the deaths were about equal. This, say the authors, may indicate that "the Jews are more anxious and visit the dispensary with slighter symptoms. . . . The lower mortality may not be due to a lower incidence rate, but to what has been stated as a fact, that the disease runs a more chronic and less fatal course in Jews than Gentiles." This is a possible explanation, but it is not the correct one. I maintain that the mortality from tuberculosis is everywhere lower among Jews, and this is so even when Jews of slums are compared with Gentiles in richer neighbourhoods. There is abundant evidence to prove this. I further contend that the lower mortality is due, not only to the greater chronicity of the disease among Jews, but to the fact that the disease tends to cure itself amongst them. That this is so is shown by the results of sanatorium treatment. Figures which I published in the paper referred to, and which Professor Pearson and Miss Moul inadvertently

omit to quote in their memoir, compare the relative percentage of cures in the Daneswood Sanatorium and in the King Edward VII Sanatorium, which admits patients of a comparatively higher social level. These show that the percentage of cures is much higher amongst the Jews than amongst the Gentiles. In other words, Jewish soil is not favourable for the growth of the tubercle bacillus. This is confirmed by the fact that the bacillus cannot be found in the sputum until the case is advanced in Jews.

The authors also deal with the comparative physique of alien Jewish and native children, and conclude from anthropometric measurements, such as stature, body weight, etc., that the Jewish child is not inferior to the average Gentile child. This is interesting information. But the authors maintain that unless the immigrant Jews show a 25 per cent. higher physical fitness than the average native they should not be allowed to enter. May I ask the authors, "Why? What is the objection?" From the eugenic point of view they have very little to fear, because they themselves state that the Jews do not as a rule intermarry with Gentiles, so that, granting that physical fitness is an hereditary character unaffected by environment, there is no risk of the native standard of fitness being lowered by the influx of alien Jews. But, further than that, I wish to repeat here the protest I have often made against accepting certain anthropological measurements as evidence of physical fitness. The only measurement of the fitness of an individual is his susceptibility to death. People who die at a higher rate and at a younger age are, on the average, physically inferior to those that die at a lower rate or at an older age. Statistics collected in different parts of the world definitely show that the *expectation of life* at all ages is higher among Jews than among Gentiles, and hence we must assume that the Jew is physically fitter than the non-Jew. Moreover, the Jewish infantile mortality is everywhere (including the worst slums) lower than the non-Jewish. Indeed, it is well known that when comparing the infantile mortalities of two neighbourhoods it is wise to ascertain the relative proportions of Jewish children in those neighbourhoods before drawing any conclusions regarding the differences in environmental conditions. Professor Pearson has always maintained that infantile mortality is unaffected by environment, that the fit survive and the less fit die, that the fit are the offspring of the fit, and vice versa. Surely the conclusion is obvious. Jewish infants, according to his own argument, die less because they are the more fit, and because they are the offspring of fitter parents.

One other point. Professor Pearson and Miss Moul discuss the relative intelligence of alien Jewish and native Gentile children, and come to the somewhat striking conclusion that, on the average, the alien Jewish child is mentally somewhat inferior to the native Gentile child. This is a very startling statement, since it is contrary to everybody's experience. "The foreign children of East London schools are universally allowed to be sharper and more intelligent than the English" is a statement everywhere accepted as true. But no doubt the authors are at one with Spinoza in defining "Truth" as "the name we give to errors grown hoary with the centuries," and with Charles Darwin they "have no faith in anything short of actual measurement." Let me, therefore, give the following figures expressing the experience of Whitechapel Foundation School: whilst of the Jewish boys 56 per cent. carried off scholarships during a certain number of years, only 25 per cent. of the Gentile children did so during the same number of years. The same is the experience of other schools.

Professor Pearson is avowedly an iconoclast; and so long as his brilliant scientific crusade discriminates between the true and false gods his campaign deserves the profound gratitude of all seekers after truth. It is much to be regretted, however, that in his great zeal he often destroys the temples of the True God and erects new shrines to the false.—I am, etc.,

W. M. FELDMAN, M.D. Lond.,
F.R.S.E.

London, W.1, Jan. 5th.

** We cannot accept the first paragraph of Dr. Feldman's letter as being an accurate summary of that part of our article which dealt with the memoir by

Professor Pearson and Miss Moul. The statement quoted by Dr. Feldman that there is a strong case against unrestricted immigration was—as we think was made quite clear in our article—a statement by the authors of the memoir, and not an inference drawn by us. We have carefully refrained, and shall continue to refrain, from premature attempts to adjudicate a very complicated question.

RETROBULBAR NEURITIS.

SIR,—Mr. Frank Heckford (*BRITISH MEDICAL JOURNAL*, January 16th, p. 93) does well to draw attention to this complaint, the origin of which is usually regarded as a mystery. The discussion reported on page 102 of the same issue offers no solution of the mystery except the negative one that it has nothing to do with sphenoidal sinusitis. My own experience confirms this, for no associated lesion is found by x rays in any of the paranasal sinuses.

My observations convince me that all cases in my practice have been due to toxæmia—nearly all of intestinal origin. The signs and symptoms have been typical of severe stasis, and where a bismuth investigation has been carried out the presence of stasis has been fully confirmed. Neuritis of the sciatic and other nerves is a well known sequel of toxæmia, and it is no wonder if, now and then, neuritis picks out the optic nerves.

It is a mistake to suppose that all cases clear up as completely as those described by Mr. Heckford; the prospects of recovery of vision depend upon prompt and thorough treatment of the stasis. Mr. Heckford does not describe the treatment used in his cases, but no doubt rest in bed, warmth, and a purge formed an essential part of it, and went far to save his patients' vision.—I am, etc.,

London, W.1, Jan. 16th.

ALFRED C. JORDAN.

HELIO THERAPY AND ACTINOTHERAPY.

SIR,—A few days ago an article written by Dr. Saleeby on the subject of ultra-violet radiation appeared in a magazine which is published once yearly. In it the following statement occurs: "Nowhere in the published literature of artificial phototherapy in any country can be found records that seriously stand a moment's comparison with those of Rollier and his followers." I suggest that this statement is misleading, and that the results obtained in the treatment of surgical tuberculosis by carbon arc light baths at the Finsen Institute, Copenhagen, published in *Acta Radiologica* (No. 4, vol. i, fasc. 4), are almost identical with the statistics of similar cases at Dr. Rollier's clinics, Leysin, mentioned in *Heliotherapy*, 1923. In a few cases the Finsen results are even better than those obtained at Leysin.

Disease.	Finsen Institute.	Dr. Rollier's Clinics.
Tuberculosis of hip-joint ...	60 per cent. recovered	70 per cent. healed.
Tuberculosis of knee ...	64 per cent. recovered	71 per cent. healed.
Tuberculosis of ankle ...	69 per cent. recovered	82 per cent. healed.
Tuberculosis of hand and wrist	87 per cent. recovered	55 per cent. healed.
Tuberculosis of elbow ...	94 per cent. recovered	93 per cent. healed.

Of the patients attending the Finsen Institute, 70 per cent. are over 15 years of age, and many of them are out-patients, often living in none too healthy homes. Dr. Rollier's patients are living in hospital under his direct personal supervision.

It is, of course, acknowledged that natural sun treatment has certain advantages in the prevention and cure of disease; but it cannot seriously be suggested that it is possible or desirable to send all tuberculous patients to Switzerland.

In my opinion it is impossible to practise heliotherapy satisfactorily in the North of England in the winter; even, as I have recently tried, by the use of "vitaglass," my great standby has been ultra-violet lamps.

Apart altogether from surgical tuberculosis, there are many conditions which require only a few exposures to ultra-violet radiation to effect a cure.—I am, etc.,

Newcastle-on-Tyne, Jan. 14th.

W. KERN RUSSELL.

THE RELATIONSHIP OF THE MEDICAL PROFESSION TO UNQUALIFIED PRACTICE.

SIR,—Dr. C. O. Hawthorne's letter in the *BRITISH MEDICAL JOURNAL* of January 16th (p. 122) does not mention the rule of English law as to the burden of proof. "He who asserts must prove." From this follows another rule—that a prisoner, even after the grand jury has found a true bill against him, is presumed to be innocent until the foreman of the petty jury returns into court and announces the verdict. No prisoner need open his mouth in court except to plead guilty or not guilty, and if he remains silent, or puts in a plea of a confusing character, the judge will order a plea of "Not guilty" to be entered, and try the case on its merits. If a prisoner is undefended the court will assist him.

A "domestic tribunal" such as the General Medical Council is bound by its own rules, but cannot set aside the law of the land, nor can it afford to dispense with the rules of evidence as set out in the late Sir James Fitzjames Stephen's little book, which I am glad to see receives high praise from Lord Birkenhead in *Twelve Judges*. For the London Hospital Forensic Medicine Lectures I have used it alone when speaking of evidence.—I am, etc.,

GEORGE JONES, M.B.,
Barrister-at-Law.

London, S.E., Jan. 15th.

LOCAL ANAESTHETICS.

SIR,—At the Eye Institution here, where we have over 1,000 cases of eye injury to treat a year, including a large number of foreign bodies, I have been testing the effect of borocaine since the communication concerning this drug appeared in the *BRITISH MEDICAL JOURNAL*.

A fortnight ago I gave it up as useless for the purpose, and I wish to corroborate the conclusion in the *JOURNAL* of January 16th (p. 83) contained in the paper by Mr. Harrison Butler and Mr. R. U. Gillan.

On the other hand, I find that butyn has a satisfactory effect, and it has this advantage, that in a large clinic printed slips may be used as prescriptions to hand to patients suffering from painful corneal abrasions and such-like conditions. Previously the Dangerous Drugs Act with regard to cocaine had rendered this relief to patients impossible.—I am, etc.,

Aberdeen, Jan. 16th.

A. R. GALLOWAY, O.B.E.,
M.B., C.M., M.A.

DENTAL DISEASE IN CHILDREN.

SIR,—In your review in the *JOURNAL* of December 12th, 1925 (p. 1139), of the Medical Research Council's report on its recent investigation into dental disease, the question is asked whether the gingivitis referred to in my statements was limited to the anterior gingivae.

May I explain that this was not so? I found comparatively few children in whom the condition of "anterior marginal gingivitis" existed alone, and was forced to include a very large number in which the inflammation was almost general.

I have referred to this on page 9, paragraph 5, of the report, explaining that in "probably half of these the slight inflammation affected all buccal gingivae in both jaws."—I am, etc.,

London, W.1, Jan. 14th.

NORMAN J. AINSWORTH.

PERIODS OF OSSIFICATION.

SIR,—Reliance is nowadays, in courts of justice, placed by lawyers on the results of x-ray examinations of the human skeleton (in the loose use of the word) for determination of the ages of minors in cases of rape, kidnapping, questions of civil and criminal responsibility, etc. The periods of union of epiphyses with the shafts of bones, of bones with each other, and the periods at which points of ossification appear after birth, are fondly imagined to be fixed and immutable.

Many authors commit themselves to the statement that the most reliable data for determination of the ages of babies, especially in earlier years and in intrauterine life, are obtainable by radiography, and the non-medical lawyer goes to court armed with formidable-looking volumes

from which he hurls statistics at the medical witnesses. *Soluntur risu tabular*. While making all allowances for Indian precocity in general and sexual development, in periods of eruption of teeth and of ossification, and for the too frequent eccentricities of development that one finds east of Suez, I find myself, after many years of impatient investigation, while not at all decrying the great usefulness of x-ray examinations in this connexion, at a loss to discover tables of statistics, Oriental or Occidental, on which to pin my wavering faith. Dogmatism is carried to excess, and I have, in my filing cabinets, plates which I take out and look long at whenever I feel tempted to forget that I am dealing, not with mathematics, but with medical jurisprudence.—I am, etc.,

WILLIAM NUNAN, M.D.,
Police Surgeon of Bombay, and Professor
of Medical Jurisprudence, Grant
Medical College, Bombay.

December 18th, 1925.

TREPANNING AND TREPHINING.

SIR,—As Dr. T. Wilson Parry, who has written so much and so interestingly on the subject, says, no name has been given to the Neolithic procedure of opening the skull, and I agree with him that my criticism of the employment of the word "trephining" which should mean an operation performed with a trephine, applies, although in a less degree, to the employment of the word "trepanning" to describe the primitive operation which was done generally by scraping, and not by boring. In recent times the Neolithic operation has perhaps been most frequently performed in some of the islands of the South Pacific, and more especially in Uvea, one of the Loyalty group, where a scraper and not a borer was always used (Mrs. E. Hadfield and other writers). The difficulty in the choice of words occurred to me some time ago when I wrote a few notes on historic trepanning, and on looking up the subject I came to the conclusion that it was incorrect to apply the word "trephining" to an operation performed before the invention of the trephine, and I am still of that opinion. Perhaps the word "trephination," as Dr. Parry says, meets the case, for this implies rather a similarity in result than in the instrument used.

However, much could be said for the employment of the word "trepanation," which would bring English writers into line with the French, who have written so much on the subject.—I am, etc.,

London, N.W.3, Jan. 9th.

H. A. CLOWES.

VITAL STATISTICS FOR ENGLAND AND WALES, 1925.

WE are indebted to the Registrar-General for the following statement regarding the birth rates and death rates and the rates of infantile mortality in England and Wales and certain parts of the country during 1925. The statement is issued for the information of medical officers of health. The birth rate and infantile mortality rate for London have been provisionally corrected for transfers.

ENGLAND AND WALES.

Birth Rate, Death Rate, and Infantile Mortality during the Year 1925 (Provisional Figures).

	Birth Rate per 1,000 Total Population.	Death Rate per 1,000 Population (Crude Rate).	Deaths under One Year per 1,000 Births.
England and Wales	18.3	12.2	75
105 county boroughs and great towns, including London	18.8	12.2	79
158 smaller towns (populations from 20,000 to 50,000 in 1921)	18.3	11.2	74
London	18.0	11.7	67

The death rate for England and Wales relates to the whole population, but that for London and the groups of towns to the civil population only.

The birth rate of England and Wales as a whole is the lowest recorded, except during the war years 1917 and 1918, while the death and infantile mortality rates are equal to those recorded in the previous year.

Obituary.

JOHN BASIL HALL, M.A., M.Chir. Cantab.,
F.R.C.S. Eng. and Edin.,
President of the British Medical Association, 1924-25;
Consulting Surgeon, Bradford Royal Infirmary.

It was with deep regret that we had to announce in our last issue the tragically sudden death of the immediate Past President of the British Medical Association, Mr. J. Basil Hall of Bradford, on Tuesday, January 12th. For a few days previously he had not been feeling well, but he continued at his work, and was to have operated on the very day he died. On that morning he was seized with a spasm of angina pectoris, and passed away in the presence of his friend and colleague, Dr. Ralph A. Lankester.

John Basil Hall came of medical stock on both sides. His paternal grandfather was Dr. Matthew Hall, who practised in Wortley, then a pleasant village near Leeds. His father, Dr. William Hall, who died in 1923 in his ninetieth year, was an honoured practitioner in Leeds and well known for his pioneer work in connexion with the feeding of poor school children. His maternal grandfather was Dr. John Bowe of Richmond, Yorkshire. Basil Hall, the second son of William Hall, was born at Leeds in 1868. From King's School, Canterbury, he went to Pembroke College, Cambridge, graduating B.A. in 1887, and studied medicine at St. Thomas's Hospital and Vienna. Having taken the M.R.C.S. and L.R.C.P. diplomas in 1890, he graduated M.A., M.B., and B.Ch. Cantab. in 1893, and in 1899 obtained the M.Ch. degree and the diploma of F.R.C.S. Ed. After qualifying he held various resident appointments at Leeds General Infirmary, including that of resident surgical officer. In 1897, as there

was not likely to be a vacancy on the staff of that hospital for some years, he decided to go to Bradford and practise as a consulting surgeon; in this he was breaking entirely new ground, as all Bradford surgery had previously been done by general practitioners. Hall worked hard, and in 1901 he was appointed honorary surgeon to the Bradford Royal Infirmary, which post he held until 1921, when at the expiration of his term of office he was placed on the consulting staff of the hospital. On that occasion he was entertained to dinner by his colleagues on the honorary staff, and was presented with a piece of plate suitably inscribed.

Matters were in a transitional state at the Bradford Royal Infirmary when Hall was appointed to the staff. He threw himself heart and soul into the task of modernizing the surgical work of the institution, and soon became

imbued with the idea that the one thing necessary was the building of a new infirmary worthy of the city. With this object in view a committee was formed, of which he was the enthusiastic chairman, and in 1908-9 a considerable sum of money was raised, and a new infirmary site on the outskirts of the city was purchased. Unfortunately, owing to a rise in the cost of building and the outbreak of the great war, matters came to a standstill. That this plan did not further materialize was one of the big disappointments of Hall's life. During the war he acted as administrator of Field House Auxiliary Hospital, Bradford, for a period, after which he was a surgical specialist with the Mediterranean Forces at the Dardanelles.

He had filled the presidential chairs of both the Bradford and Leeds Medical-Chirurgical Societies, and he was also a former Chairman of the Bradford Division of the British Medical Association. In 1924, when the Annual Meeting of the Association was held at Bradford, Basil Hall was unanimously nominated by the Division for the presidency. He threw himself whole-heartedly into the necessary heavy work of preparation, and the undoubted success of the Bradford meeting was largely due to his inspiring enthusiasm. During his presidential term of office the Ontario Medical Association invited him to address its annual meeting in Toronto, and from Canada he proceeded to the United States, where he represented the British Medical Association at the annual meeting of the American Medical Association and gave an address. While in the United States he was elected a Fellow of the American College of Surgeons. Just prior to his departure for Canada he was elected, on April 2nd, to the Fellowship of the Royal College of Surgeons of England, an honour which gave him extreme gratification.

As a surgeon Basil Hall was a strong advocate of the clinical aspect of diagnosis, and regarded modern adjuncts thereto, such as x rays and biochemical tests, as good servants but bad masters. As a diagnostician he was regarded by his professional colleagues as very sound. In his surgical operations he was neat, dexterous, and resourceful, and he was not satisfied with dismissing his cases at the end of treatment, but was very keen on following the after-care and end-results. He was extremely businesslike and methodical in all he did, and his case-books were models of neatness and funds of information.

As a man, under a veil of gentle cynicism Hall concealed the kindest of hearts: he had ever a feeling of compassion for the "bottom dog," and weaker brethren in him had always a friend. He hid his light under a bushel, and many were the unknown services which he rendered gratuitously. To those who were admitted to the privilege of his friendship his genial kindness and hospitality were

[Walter Scott, Bradford.

J. BASIL HALL, M.Chir., F.R.C.S.,
Past President, British Medical Association.

His many friends will hear with regret of the death, on December 24th, 1925, at Mentone, France, of Dr. SUTHERLAND REES-PHILIPPS, the late medical superintendent of the Holloway Sanatorium, Virginia Water. Dr. Rees-Philipps was 78 years of age. Since his retirement he had been actively engaged in outdoor pursuits, and was particularly fond of gardening, but was constrained latterly to go abroad for health's sake. Despite this, his strength had been for the last six months steadily declining, and recently he underwent a serious operation, from which he did not completely recover. Dr. Rees-Philipps was educated at Cheltenham College and the Royal University of Ireland, where he graduated M.D., M.Ch. in 1871. After qualifying he held several hospital appointments; but very soon his interests led him to adopt the practice of psychiatry. He was appointed to the staff of Devon County Asylum, thence to the Three Counties Asylum, Arlesley, as senior assistant medical officer. Later he was appointed medical superintendent of Wonford House Hospital, Exeter, which post he relinquished to become the first medical superintendent of the Holloway Sanatorium. Of this hospital he undertook the organization and equipment with his customary enthusiasm. Dr. Rees-Philipps was an active member of the Royal Medico-Psychological Association until his recent illness, and a Fellow of the Medical Society of London. He leaves a widow, with whom deep sympathy is felt in her loss.

Dr. GEORGE CHAPMAN, who had reached the age of 102, and was probably the oldest medical practitioner in England, died at Hall Green, Birmingham, on January 13th, after an illness lasting only four hours, prior to which he had been in his usual health and was out walking on the previous day. Dr. Chapman received his medical education at Queen's College, Birmingham. He obtained the diploma M.R.C.S. in 1866, and in 1868 the L.S.A. He spent his whole life in the Midlands, commencing practice at Brierley Hill, Staffordshire. He remained there for many years, and was public vaccinator and medical officer to the guardians. Leaving Brierley Hill in 1883, he subsequently practised in Armitage, near Rugeley, and became surgeon to the Rugeley Cottage Hospital. Sixteen years ago he retired from practice, and had since lived with his daughter at Hall Green, Birmingham. Dr. Chapman maintained to the last a keen interest in public affairs and politics, and was able to record his vote at the last parliamentary election. His wife and his son, Dr. H. Dugard Chapman, both predeceased him.

Universities and Colleges.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

Dr. Axham.

At a meeting of the Royal College of Physicians of Edinburgh, held on January 19th, the suspension of the licence of Frederick W. Axham, which was imposed on May 7th, 1912, was removed. The motion put before the College and carried by a majority was as follows:

"The College having on the 7th day of May 1912 determined on good cause shown that Frederick William Axham, a Licentiate of the College, of Morden, Dollis Park, Church End, Finchley, N., should be suspended *sine die* and deprived until the said suspension is removed or remitted of all the rights and privileges which as a Licentiate he enjoyed,—it is now resolved by the College (on proof submitted that the said Frederick William Axham has abstained for the last five years from the practices which led to his suspension and will not resume them) that the said suspension be removed as from this date."

UNIVERSITY OF OXFORD.

Degree Days.

The degree days during the year are as follows:—Hilary March 27th. Trinity Term: May 22nd; Thursday, June congregation will in each case be held at 2.30 p.m. academic 13th and Saturday, rd. The

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A quarterly Council meeting was held on January 14th, when the President, Sir John Bland-Sutton, Bt., was in the chair.

Lecturers.

Sir Berkeley Mornihan was appointed Hunterian Orator for 1927. Sir John Lunn-Thomas was appointed Bradshaw Lecturer for 1926,

and Professor G. Elliot Smith F.R.S., was nominated as Thomas Vicary Lecturer for the ensuing year.

Court of Examiners.

Mr. Raymond Johnson wrote a letter resigning from the Court of Examiners. The resignation was accepted, to take effect from March 10th next, and the vacancy thus occasioned will be filled up at the ordinary Council on March 11th.

The Case of Mr. F. W. Axham.

A further application from Mr. F. W. Axham for restoration to membership was considered, but the Council did not see fit to rescind the resolution of July 13th, 1911, removing Mr. Axham from the membership of the College.

The Museum.

It was announced that for the remainder of January and during February the museum will be kept open until 5, instead of being closed at 4 p.m.

L.D.S. Gown.

A gown for Licentiates in Dental Surgery was instituted, the gown to be of black stuff similar in shape to the Fellows' and Members' gowns, with facings of crimson cord and with a sleeve looped with crimson cord.

Diplomas.

Diplomas were granted jointly with the Royal College of Physicians of London in the following subjects:—Public health to sixteen candidates, tropical diseases to four candidates, psychological medicine to four candidates, and otology to four candidates.

Primary Fellowship Examination.

At the examination in anatomy and physiology for the Fellowship concluded on December 17th, 1925, 129 candidates were examined, of whom 40 were successful and 89 were rejected.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At a special meeting of the President and Fellows held on January 15th the following candidates were admitted Licentiates in Medicine and Midwifery of the College:

Miss Ellen Kiernan, Mrs. Ellen Ryan.

The Services.

NAVAL MEDICAL COMPASSIONATE FUND.

At the quarterly meeting of the directors of the Naval Medical Compassionate Fund, held on January 19th, when Surgeon Vice-Admiral Sir Joseph Chambers, K.C.B., C.M.G., Medical Director-General of the Navy, was in the chair, the sum of £105 was distributed among the several applicants.

DEATHS IN THE SERVICES.

Fleet Surgeon Alexander George William Bowen, R.N. (ret.), died at Plymouth on January 4th, aged 62. He was educated at Guy's and at Cambridge, where he graduated as B.A. in 1884; and as M.B. and B.Ch. in 1889. Entering the navy as surgeon on November 11th, 1891, he served on H.M.S. *Partridge* in the West Indies, and with the Plymouth Division of Royal Marines. Becoming staff surgeon in November, 1899, he served in H.M.S. *Beagle* on the Cape and West African stations, and later in the cruiser *Amethyst*. He became fleet surgeon in November, 1907, and served as such in the battleships *Canopus* and *Agamemnon*. He retired in 1912. During the recent war he served as a temporary major in the R.A.M.C.

Medical News.

SIR JAMES BERRY will deliver the Hunterian Lecture at the Medical Society of London to be held in the Medical Association House, Tavistock next, January 25th, at 9 p.m. The lecture will be some clinical aspects of simple goitre, with remarks on its causation; it will be illustrated by the epidiascope. A discussion will follow in which Dr. Strickland Goodall, Mr. Dunhill, and Dr. Scott Williamson will take part.

ON January 28th Dr. H. C. Cameron will lecture for the Fellowship of Medicine on catarrhs and the catarrhal child, at 5 p.m., in the lecture hall of the Medical Society of London, 11, Chandos Street. The London Lock Hospital will hold a comprehensive course in venereal diseases from February 1st to 27th. A two weeks' afternoon course, beginning on February 1st, will be given at the Blackfriars Hospital for Diseases of the Skin. A combined course in diseases of children, in which the Paddington Green Children's Hospital, Victoria Hospital, and the Children's Clinic will be participating, will be given from February 8th to 27th. A late afternoon course (4.30 to 6) for general practitioners has been arranged at the London Temperance Hospital from February 8th to 19th. A general intensive course in medicine, surgery, and the special departments will be held at the Queen Mary's Hospital, Stratford, from February

15th to 27th. A copy of each syllabus of these courses, and of the programme of the general course arranged by the Fellowship, may be had from the Secretary at 1, Wimpole Street, W.1.

PROFESSOR A. V. HILL, F.R.S., will begin a course of six lectures on the physiology of muscle at University College, Gower Street, W.C.1, on Monday, February 1st, at 4 p.m. They will be continued on succeeding Mondays at the same time. Admission to the lectures is free without ticket.

DEMONSTRATIONS are being given at the Maudsley Hospital, Denmark Hill, S.E., on Monday and Wednesday afternoons, at 2.30; clinical discussions are held in the wards on Tuesday mornings at 11.30, and there is a monthly meeting on the last Friday of each month, at 4.30 p.m., at which a group of patients from one of the London County Council mental hospitals is shown. All these meetings are free to medical practitioners and students.

SIR ROBERT CHARLES BROWN, F.R.C.P., F.R.C.S., consulting medical officer to the Preston Royal Infirmary, of whom an obituary notice appeared in our issue of December 5th, 1925 (p. 1093), left estate of the gross value of £80,716. He bequeathed £1,000 free of legacy duty to the Directors of the Cambridge Research Hospital, and made bequests of £100 each to many charitable institutions. Two-thirds of the residue of his estate is left to the Preston Infirmary Convalescent Hospital, Lostock Hall.

THE thirty-eighth Congress of the German Society of Internal Medicine will be held at Wiesbaden, under the presidency of Professor Pässler of Dresden, from April 12th to 15th, when the following subjects, among others, will be discussed: (1) modern treatment of syphilis of the nervous system, introduced by Spielmeyer of Munich and Wagner-Jauregg of Vienna; (2) the blood as a clinical mirror of somatic processes, introduced by von Schilling of Berlin; (3) asthma, introduced by Dr. Klewitz of Königsberg.

INTERNATIONAL post-graduate courses will be held in March in Berlin, and will include clinical lectures on internal medicine, a fortnight's course on diseases of children, a week's course in nerve diseases, and a special course in throat, nose, and ear affections. Further details may be obtained from the International Post-Graduate Course Office, Kaiserin Friedrich-Haus, Luisenplatz 2-4, Berlin N.W.6.

A MEDICAL congress under the name of "Journées médicales tunisiennes" will be held at Tunis this year, from April 2nd to 5th, when the following subjects will be discussed: (1) gastro-duodenal surgery; (2) Mediterranean fever; (3) prophylaxis and treatment of measles; (4) trachoma. The subscription is 100 francs. In connexion with this congress various excursions will be arranged to surrounding centres of interest, including Carthage, La Marsa, El-Djem, and Sfax. Further information can be obtained from Dr. Gerard, Bureau d'hygiène, Tunis.

THE first congress of the medical press of Latin countries will be held in Paris towards the end of 1926, when the following questions, among others, will be discussed: (1) Unification of the terminology and bibliography in medical literature, introduced by MM. Miraudo (*Journal de médecine et de chirurgie pratiques*) and Tecon (*Revue suisse de médecine*). (2) Copyright in the medical press, introduced by M. Ardette (*La Presse médicale et de la Presse française*) of the Paris Court of Appeal.

THE preparation, organization, and transactions of medical congresses, introduced by M. le Sourd (*Gazette des Hôpitaux*), and J. de Azevedo (*A Medicina Contemporânea*). Further information can be obtained from Dr. L. M. Pierra, 12, Rue de Babylone, Paris VIIe.

THE fifty-ninth congress of the learned societies of Paris and the French departments will be held at Poitiers on April 6th.

A CLUB of medical chess players is to be formed in Paris. Those wishing to join should communicate with Dr. Somen, 113, Avenue Saint-Martin, Paris IVe. There is no subscription.

THE centenary of the birth of the celebrated physiologist, Felix Hoppe-Seyler, was recently celebrated in the physiological Institute of Tübingen University.

PROFESSOR HANS EPPINGER, formerly the first assistant of Professor Weigekbach in the medical clinic at Vienna, has succeeded Professor de la Camp as director of the medical clinic at Freiburg.

DR. CLAUDIUS REGAUD, director of the Paris Radium Institute, has been nominated doctor *honoris causa* of the free University of Brussels.

AS the result of a matinée organized at Daly's Theatre on January 14th, over £900 was raised on behalf of the Elizabeth Garrett Anderson Hospital for Women. An effort is being made to obtain £75,000 for the building of new pathological and x-ray departments and other much needed accommodation.

DR. T. A. MCCULLAGH, Bishop Auckland, has been appointed Deputy Lieutenant for the County of Durham.

APPLICATIONS from over 300 surgeons have been received for the next International Congress of Surgery, which is to be held at Rome from April 7th to 10th, the distribution, according to their nationality, being as follows: Belgium 33, Canada 2, Czecho-Slovakia 6, Cuba 2, Denmark 10, Egypt 8, France 70, French colonies 7, Great Britain 59, Greece 1, Holland 24, Ireland 6, Italy 20, Poland 9, Portugal 6, Rumania 4, Russia 4, Spain 14, Sweden 8, Switzerland 28, United States 12. Two sea voyages for medical practitioners round the Mediterranean have been organized by the *Bruzelles-Médical* in connexion with this congress. The first voyage, lasting thirty-one days, will start from Marseilles on March 5th, and the second, lasting thirty-three days, will leave the same port on April 15th. The places visited will include Naples, Alexandria, Jaffa, Beyrouth, Smyrna, Constantinople, Constanza, the Piræus, and Malta. The charge for each voyage is 4,200 francs. Further information can be obtained from Dr. Bernard, 62, Rue Froissart, Brussels.

DR. CHARLES DEJEAN of the Montpellier Faculty of Medicine has been awarded the Cirincione prize in the international ophthalmological competition at Rome.

ACCORDING to the *Japan Medical World* the number of cases of beri-beri in the Japanese army has risen from 3.43 per 1,000 in 1914 to 10.47 in 1923, and in the navy from 1.36 per 1,000 in 1914 to 2.40 in 1923.

THE fall in the birth rate in Sweden, which has been a source of considerable anxiety in that country, is shown by the following figures. During the period 1891 to 1900 there were 26.3 births per 1,000 persons. From 1911 to 1920 this figure fell to 17.8, and in 1924 to 12.6 per 1,000. The death rate, on the other hand, has fallen from 19.1 to 11 per 1,000.

FROM July 26th to September 12th, 1925, 1,959 fatal cases of plague occurred in Java; and 6,268 cases of plague, with 4,421 deaths, and 7,919 cases of cholera, with 4,789 deaths, occurred in British East India from August 16th to September 19th.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, **British Medical Association House, Tavistock Square, W.C.1**, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the **British Medical Association** and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the **British Medical Association** is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

ORAL STENOSIS.

MR. FRANK COLEMAN (London) writes: I would like to suggest a simple method of treatment that would, I believe, be effectual in restoring the patency of the mouth in the case described by Dr. Hoyte (*JOURNAL*, January 9th, p. 15).

At the position of the angle of the mouth on each side make a circular opening into the oral cavity with an antrum perforator or some similar instrument and enlarge each opening to the size of a lead pencil or slightly larger (approximately 3/8 in.). Insert a piece of drainage tubing (approximately No. 14) through each opening, so that the free end passes well into the oral cavity, then cut off each tube beyond the skin surface and retain in position. Flanged empyema tubes would serve the purpose well and be easy to retain in position. Leave the tubes *in situ* for about three or four weeks, or until the canals are completely cicatrized, changing the tubes when necessary for cleaning. A director is then passed from one lateral opening to the other

and the intermediate tissues are divided horizontally or excised on the groove of the director, thereby throwing the three apertures into one. The scar tissue at each angle of the mouth would prevent adhesions from re-forming, and the occasional passage of a lubricated soft rubber tube or the patient's own tongue would assist in keeping apart the more recent raw surfaces until healing or scarring had taken place. The artistic result would depend upon correctly estimating the sites for the future angles of the mouth when making the lateral perforations. I have employed the principles of this method (which I suggested in 1910) for many years in dealing with the lateral perforations of the gums and the cheek, which sometimes prevent the wearing of a denture, but admit that the present method of using an epithelial inlay, as practised at Sidcup, is more advantageous for extensive adhesions.

BENEDICT'S TEST: AN EXPLOSION.

"A. G. N." asks for an explanation of the following: Using this test solution (recently supplied) for the presence of sugar in the urine, I have on several occasions got a white flocculent precipitate with slight albumin in the urine and also without any albumin being present, though sugar is present. On two occasions an explosion has occurred—one with no albumin but with sugar, and the other with slight albumin but no sugar. In the latter case the test tube was blown out of my hand.

"A. G. N." writes later to say that the firm who supplied him state that they sent a quantitative solution of Benedict's test, and that this does throw down a white precipitate with sugar.

No explanation of the explosion is to be found in any suggestion of chemical reaction, even if it be supposed that the solution contained a foreign constituent. There is, however, nothing extravagant in the supposition that the explosion resulted from overheating. Explosions resulting from the overheating of liquids which do not boil freely may assume a violence resembling that caused by chemical decomposition. Alkaline liquids are particularly liable to boil percussively. The cause lies in the interfacial tension between the liquid and the surface of the glass test tube, where the heat on meeting the liquid ought to generate bubbles of steam freely and evenly. But particles of solid matter, for such particles are necessary as nuclei for the formation of vapour. Accordingly the cleaner the liquid the more unevenly it boils, and if incipient boiling is delayed the liquid becomes overheated to a greater or less degree, favoured by shallowness of the vessel. Quiet ebullition is until a sudden burst of boiling is induced. Quiet ebullition is proportioned to its volume the more it becomes liable to bumping. The addition of dust favours steady boiling. It is useful to add a few granules of powdered pumice as a corrective. Alkaline liquids usually boil with intermittent bursts because of their cleansing action on the glass and the consequent removal of solid impurities. There is also a peculiar solvent action of alkali on glass, which adds to the effect. It is usually worse when the liquid contains much saline matter, and some kinds of glass are worse than others, particularly certain thick-walled test tubes. In extreme cases explosions of remarkable violence may take place from the superheating of liquids.

GOUT, FIBROSITIS, AND NEURITIS.

"A. W. G." asks for information as to the following points relating to gout and its complications, especially fibrositis and neuritis: (1) Does a warm, dry climate have any beneficial effect? (2) If so, which are the localities advised—(a) in the British Isles; (3) in Europe; (4) in Africa, north or south; (5) other places? (6) Does living in proximity to the sea, rivers, lakes, or wooded country have any effect? (7) The effect of nature, of soil and drainage. (8) Exercise—outdoor occupation entailing wet feet and damp clothes. He asks for personal observation, literature, statistics, and a recommendation as to what to read on the subject.

RECURRENT URTICARIA.

Dr. I. DAVID (Colombo) writes: Recently I had a case similar to that recorded by "N. L." (BRITISH MEDICAL JOURNAL, November 21st, 1925). It yielded to an intramuscular injection of sulpharsenol, followed by an intravenous injection of calvarian (0.9 gram). By mouth he was given melubrin and calcium lactate.

LETTERS, NOTES, ETC.

LIFE POLICY HOLDERS MEDICAL OVERHAUL.

SINCE July, 1923, the Legal and General Assurance Society has had a scheme for the medical overhaul of life policy holders, a procedure which has been adopted with satisfaction by some American insurance offices. The process of popularizing the scheme is entitled *The Sere, the Yellow Leaf*. The author of these essays written by Dr. Leonard Williams. The latest protests against the tendency of many men and some women to allow themselves to get old, or to die at an age when they ought to be beginning to live, to the detriment, incidentally, of their insurance society. He disapproves of a life of *otium cum dignitate*, especially when combined with penury. His remedy is exercise; and if golf and tennis are too expensive, or cycling too dangerous,

he recommends the adoption of a system of physical exercises, or the practice of walking, if possible with some end in view. The Legal and General Assurance Society sends these booklets free to policy holders, as it is to the interest of the society that the policy holder should maintain good health. For the same reason the society invites its life policy holders to present themselves once a year for a medical overhaul which will not infringe the rights of the ordinary medical attendant.

CANCER PREVENTION: FREE CLINICS.

Dr. JOHN BROWN (Blackpool) writes: Dr. Young's letter in the JOURNAL of December 12th, 1925 (p. 1147), has met with ready response and approval by those who have devoted many years to the cancer problem. The results of free clinics clearly demonstrate that in the city of Detroit the majority of the growths were innocent, but there were some in the precancerous stage, and 42 out of 1,100 persons were cancerous. The methods adopted in Detroit can readily be carried out in this country. Already the public is being prepared for it. The medical and health authorities of the city have been doing the public on the diagnosis of tumours in the precancerous stage. My personal experience and correspondence with doctors in all parts of this and other countries show that there is a far more hopeful outlook. I am convinced that the time is ripe for the Ministry of Health to begin these free clinics, so that all persons with suspicious growths can have expert advice.

THE NATURAL FOOD OF A BABY.

Dr. W. Y. DAVIDSON (Birmingham) writes: I wholly disagree with the remarks of Dr. MacLachlan (BRITISH MEDICAL JOURNAL, January 16th, p. 126). I have no hesitation in saying that the best and cheapest substitute for the mother's milk is undiluted cow's milk. In 1914 I was greatly struck by an article in the *Practitioner's Encyclopaedia of Medicine and Surgery* (Murphy: Oxford Medical Publications) on the artificial feeding of infants, by Dr. Frederick Langmead of Great Ormond Street Hospital. He recommended undiluted citrated cow's milk (2 grains of sodium citrate to the ounce). With a slight modification I have used this method since 1914, with the very best results. The modification consists in the addition of a teaspoonful of extract of malt to each feed. The most delicate and puny babies will take this and thrive on it. The addition of the malt is of great advantage, as it gives the milk a pleasant flavour and also aids digestion. I have never known a case where this diet disagreed with an infant.

ONE HUNDRED YEARS OF MEDICAL JOURNALISM IN BORDEAUX.

The issue of the *Journal de Médecine de Bordeaux et du Sud-Ouest* for November 1st, 1925, forms the centenary number of this periodical, which was founded in 1824 under the name of *Journal Médical de la Gironde*. Since then its title and format have changed several times, and during certain critical stages of French history—namely, towards the end of the Restoration, in 1870, and again in 1914—its publication was temporarily suspended. After a long period of existence as a monthly it became a weekly publication, and subsequently a fortnightly, as it is at present, when it forms one of the leading French medical journals, with a circulation of 20,000 copies. The centenary number contains interesting articles on medical journalism at Bordeaux before 1850 by Dr. Pierre Mauriac, on medicine and surgery at Bordeaux from 1870 to 1924 by the editor, Dr. Xavier Arnozan, on medical instruction at Bordeaux during the last hundred years by Dr. H. Verger, and articles on the last hundred years in neurology, dermatology, ophthalmology, otolaryngology, obstetrics, gynaecology, children's diseases, and medical electricity by the present occupants of the chairs devoted to these subjects. The text is interspersed with numerous portraits of the medical celebrities of Bordeaux during the last hundred years, including Jean Hameau, to whose great contributions to medical science we referred on May 17th, 1924 (p. 871); Guérin, a pioneer in ophthalmology, Elie Gintrac, an eminent general physician and dermatologist, as well as contemporary specialists such as Professors Régis, Pitres, Moure, Dubreuilh, and Bergonié.

RENEWAL OF MOTOR LICENCES.

For the benefit of motorists who are not well acquainted with the more important points in the present system of licensing and registration of cars and motor cycles, the Automobile Association is issuing a booklet entitled *Your Motor Tax at a Glance*, which shows the amounts due for quarterly licences, licences for less than a quarter, and whole-year licences. Information is given also concerning the allowances on old cars, refunds for surrendered licences, and the procedure for renewing licences. Copies may be had, gratis, on application to the Secretary, the Automobile Association, Fannum House, New Coventry Street, W.1.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 38 and 39. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at pages 31 and 32.

A British Medical Association Lecture ON THE NEW OUTLOOK ON CANCER.

DELIVERED BEFORE THE SHEFFIELD DIVISION ON
DECEMBER 11TH, 1925,
BY

W. CRAMER, D.Sc., Ph.D., M.R.C.S., L.R.C.P.

THE PROBLEM.

If we wish to explain a problem we must begin by formulating it. That seems a trite and commonplace observation to make. But it is a step which has been omitted frequently by those who have put forward "cancer theories." To many people cancer seems to be an abstract conception rather than a concrete, well defined, pathological phenomenon. How often have we not read in the past, even in the quite recent past, some article or book on cancer beginning with the lament that we know nothing about cancer. Having thus ingeniously disposed of everything concerning cancer that requires explanation, the author lifts his bonnet and his pet bee begins its flight. Of such writers it can truly be said that "they darken counsel by words without knowledge." I have always admired the courage with which a writer of that type advertised his ignorance. For as a matter of fact we know a good deal about cancer. As a result of the experimental investigation of cancer which began only twenty-five years ago a large number of facts were discovered. The difficulty was to find an explanation which would account for all the essential features of cancer, especially as some of the phenomena appeared to be contradictory. I propose, therefore, to begin by defining cancer as a pathological problem, and to state as briefly as I can the fundamentals, so far as they are known, of the pathology of cancer which must be accounted for by any satisfactory explanation of cancer.

We may begin with the fact on which the whole treatment of cancer by surgery is based: the local origin of cancer. At its inception cancer is localized. It is for this reason that we are entitled to say that cancer is a curable disease if it is diagnosed and removed in its early stage.

If we examine an early carcinoma of the skin or the tongue, where an early diagnosis is relatively easy, we find in a sharply circumscribed area a proliferation of the epithelial cells which grow down into the underlying tissue—muscle in the tongue, connective tissue in the skin. The cells which take part in this cancerous proliferation retain their special biological character. Thus, if the cancer cells are derived from the skin they continue to keratinize. Even in the metastases the cells continue to grow as the same type as that in which they originated. In the mouse most tumours are derived from the mamma, and one might expect, therefore, that on repeated transplantation they would converge to a common type of mammary tumour. But this is not so. Some mammary tumours showed from the beginning a very rapid growth and have maintained this rapid growth through twenty years of transplantation. Others, again, began as slowly growing tumours and still show the same slow rate of growth. There are also strains which at one time grow rapidly, then pass into a phase of depression with slow growth, from which quite spontaneously they recover to repeat the cycle in fairly regular intervals. In each propagated strain of mammary tumours the cells retain also their characteristic arrangement through twenty or more years of propagation, so that it is possible to identify a particular strain by merely looking at the histological preparation. One carcinoma of the mamma was characterized by cells containing glycogen. To-day, after fifteen years of transplantation, the cells of this tumour still continue to form glycogen, showing that we are still dealing with the descendants of the original tumour cells. There is an apparent exception to this statement. In a few

strains of transplantable mouse carcinomata it has been observed¹ that a sarcoma developed from the carcinoma. But this exception is, as stated, only an apparent one; for a careful study of this process, first by Haaland² and later by Russell,³ has shown that the sarcoma cells are not derived from the carcinoma cells, but from the connective tissue cells of the stroma which is supplied by the new host every time a tumour is transplanted. As the result of the more rapid proliferation of the sarcoma cells the carcinoma is gradually replaced by a sarcoma. In these cases, therefore, there is a transformation of normal tissue into malignant tissue by a neoplasm. But the cells which acquire malignancy as the result of this transformation again retain their specific biological character.

All these facts point to the same conclusion—namely, that a neoplasm is made up of the descendants of a few cells which have acquired the power to grow in an aimless, lawless manner. The problem which we have to explain is not merely that the cancer cell has acquired the power of growth. It is a growth which does not subserve the physiological needs of the body and is not controlled; it is a lawless, aimless growth. The cancer cells seem to be possessed of an irresistible impulse to grow, and by doing so they destroy the tissues and organs and eventually the organism in which they grow. There is no evidence of additional factors, such as specific cancer toxins or ferments, having a deleterious influence on the organism. Another striking fact is that the growth of a neoplasm is independent of the nutrition of the organism in which it grows.^{4,5} Thus conditions of nutrition which will bring about a progressive marasmus and eventually the death of the animal in a state of inanition—such as partial or complete starvation, a deficiency in specific amino-acids, such as tryptophane, or of vitamins—do not arrest the growth of cancer cells in the starved animal. This indicates that the impulse to grow resides within the cancer cells.

This aimless, lawless, irresistible growth, then, is one of the central problems of cancer. It would have been feasible to explain cell growth by postulating a specific organism if the disease were limited to only a few zoological species and could be transferred, like other microbial diseases, from one species in which it occurs to another. But cancer is characterized by this apparent paradox: while the disease is very widely distributed throughout the whole vertebrate kingdom, it cannot be transferred even from one closely related species to another by the inoculation of cancerous material. It is not so very long ago—only twenty-five years—that the belief was firmly held that cancer was a disease peculiar to man. As one of the few survivors of the early days of experimental cancer research I remember how the attempt to study cancer in animals was received with derision by many who claimed to be authorities on the subject. We owe it to the work of Bashford and Murray,^{6,7} and to the support which they received from the Executive Committee of the Imperial Cancer Research Fund, under the chairmanship of Sir William Church, that the investigation of cancer was placed on an experimental basis by demonstrating the essential similarity of the disease in man and in animals. Now we know that the disease may develop spontaneously in fishes, amphibians, reptiles, birds, and mammals. In all these classes of animals the disease exhibits the same fundamental features: a lawless, infiltrating destructive growth, having a local origin. But while the cells of probably all vertebrates are capable of undergoing the cancerous change, we cannot transmit the disease from one species to another by taking, for example, the cancer cells of a mouse and inoculating them into a rabbit, or the more closely allied rat. Attempts have frequently been made to transmit the disease from man to animals by inoculating human cancer material into mice, rats, rabbits, guinea-pigs, dogs, and monkeys. All such experiments have been uniformly negative.

This paradox—the wide zoological distribution on the one hand, the narrow limitation to one species of the transmission of the disease on the other hand—distinguishes cancer from other microbial diseases, and, as we shall see presently, has until recently been the insurmountable obstacle to the parasitic theory of cancer.

EXPERIMENTAL PRODUCTION OF CANCER.

There is another feature in the experimental pathology of cancer which distinguishes it sharply from the ordinary microbial diseases. If in a disease of undoubted microbial origin we take a piece of infected tissue and inoculate it into another animal, we reproduce the disease *ab initio* in the second animal. Thus, if we inject tuberculous human material into a guinea-pig we reproduce the disease *ab initio* in the guinea-pig. If we take an infective granuloma—a mass of connective tissue which has been formed in response to an infective agent—and inoculate it into another animal, the inoculated connective tissue cells die and the infective agent stimulates the connective tissue of the new host to form a new granuloma. Again, we have reproduced the disease *ab initio*. But if we transplant a carcinoma or a sarcoma, the transplanted cells themselves continue to grow. The tumour which grows is composed, not of the cells of the host, but of the cells of the animal in which the tumour originated. The cells of many of the mouse tumours which are now being propagated in the various laboratories belong to animals which may have died fifteen or twenty years ago. One might say that the cancer cell has gained immortality. This experimental method enables us to study the growth of a cancer once it has developed, and to submit the growth of cancer cells to various conditions. But, as has already been pointed out, it does not reproduce the disease *ab initio*.

In order to elicit cancer *de novo* a different experimental method must be applied. It is based on the experimental demonstration, first by Fibiger⁸ and later by Yamagiwa and Ishikawa,⁹ that cancer is produced by chronic irritation of a special kind. If a small area of the skin of the mouse is subjected to chronic irritation by painting it with tar twice or three times weekly over many months, a typical epithelioma develops in 60 to 80 per cent. of the treated animals. During the first three or four months no macroscopic changes are visible in the painted area, although microscopically hyperplasia of the epithelial cells of the epidermis and of the hair follicles has been demonstrated. Later, in the fifth month, a small wart may appear in some animals. There may be several warts. If painting is then discontinued—it may even be discontinued, as Dr. Leitch¹⁰ has shown, before any warts have appeared—the warts grow; if there were several they coalesce, and may develop eventually into a typical carcinoma with a hard infiltrating margin. If the animal lives sufficiently long, metastases may be found in the lymph glands and lungs. In some cases the tumour is of the benign papillomatous type. The length of time necessary to produce this effect differs greatly in different individual mice: it varies from five months to nine months. Some mice appear to be completely resistant to the effect of tarring and never produce either a wart, a papilloma, or a carcinoma.

It is known that tar workers frequently develop multiple warts of which one may become cancerous. Shale oil workers are subject to the same risk,¹¹ and, as Dr. Leitch¹² has shown, shale oil on prolonged application to mice will also produce cancer. It is surely a significant fact, demonstrating the identity of the disease in man and animals, that the same agents which produce cancer in man will also produce cancer in certain species of animals. The similarity goes even further: in mice it requires on the average six months from the onset of chronic irritation until cancer begins to develop. As the span of life of a mouse is about three years, this latent period amounts to one-sixth of the span of life. In man, with a span of life of seventy years, the period of induction is correspondingly long—ten to twenty years. There are exceptions. A few human cases are on record in which only a few weeks or months have elapsed. In one particularly striking case¹³ a spurt of oil tar lodged in a man's nostril; a fortnight later he produced a carcinoma at that site. Chorion-epithelioma of the testis, a tumour that obviously requires a short period of induction, has been produced in the guinea-pig.

American scheme of the Le...
protests against the tendency of induction. On the whole the insurance society. He disapproves cancerous as the result and if golf and tennis are too expensive.

of induction throws an altogether new light on one very characteristic feature of cancer—namely, its peculiar age incidence. Cancer is a disease of middle and old age; it is rare in the young, but becomes more and more frequent as age advances. Formerly this was attributed to the onset of senility in the tissues and the cells. But it explains itself much more simply as the result of the long period of induction. The carcinoma in the stomach of a man of 50 probably had its origin in a chronic irritation which affected the stomach ten or even twenty years earlier. There are other forms of chronic irritation which may lead to cancer. I can only mention them in passing: in man x rays, heat (the kangri cancer), cancer of the bladder in aniline workers, cancer resulting from parasites such as bilharzia and *Trichina spiralis*. It is perhaps not sufficiently well known that a number of cases are on record¹⁴ in which an infection with *Trichina spiralis* was followed after many years by the development of a cancer. The sites affected were mamma, lip, and pleura. In every case the neoplasm was a carcinoma, and in several of the cases living trichinae were found in the tumour. The period of induction was again very long—a minimum of seven years and a maximum of twenty-five years. In animals, Fibiger was the first to induce experimentally cancer in the stomach of rats by means of a nematode—*Spiroptera neoplasticus*. Bullock and Curtis¹⁵ subsequently produced sarcoma of the liver in rats by feeding them with the eggs of *Taenia crassicolis*. The sarcomata arise in the wall of the cyst enclosing the cysticercus.

SYSTEMIC FACTORS.

One of the most important and significant observations made as a result of the work on experimental tar cancer we owe to Dr. J. A. Murray.¹⁶ One would think that an animal which has readily responded to tar painting by the development of a cancer would be at least equally susceptible to the effects of a second tarring, or perhaps even more susceptible. This was put to the experimental test by removing by operation the tar cancer which had developed in a number of mice and then subjecting these animals to a second course of tarring. To his surprise Dr. Murray found that these animals did not develop cancer at all, the skin at the painted area becoming merely atrophic. He then took a number of mice in which a mammary carcinoma had developed spontaneously, removed the growth by operation, and subjected the mice to tarring. The same result was obtained: the mice were so resistant to tarring that no tumour developed during the period of survival. This shows clearly that once the body has developed a malignant new growth in one organ, it has become resistant against the subsequent development of a second neoplasm in any other part of the body, though it has not become resistant to the growth of the first tumour in other parts of the body. This accounts for the rarity of multiple tumours in different organs. Thus cancer of the breast alone and cancer of the uterus alone are frequent in women. But cancer of the breast and uterus in the same woman is rare. It is curious that this fact seems to have escaped clinicians and statisticians. Multiple tumours, when they do occur, affect almost always the same organ and tissue, and are then due to the tissue being subjected to chronic irritation at different sites simultaneously. Experimentally there is no difficulty in producing multiple cancer of the skin by painting simultaneously different areas of the skin by resistance to cancer of which I have spoken manifests itself only if chronic irritation is applied successively. This observation indicates that it is possible to induce a resistance or immunity against the development of cancer. From this point of view it would be interesting to follow the history of patients who have been operated on successfully for, say, a carcinoma of the tongue or of the breast, so as to find out whether they have developed subsequently a cancer in some other organ.

These observations give evidence that the genesis of cancer may be determined by systemic factors, although in its inception the disease is, as we have seen, localized. I have recently obtained further evidence of the existence of such systemic factors in normal animals, in which it has been possible to induce experimentally the reverse condition of

diminished resistance to the genesis of cancer. The conclusion that the development of cancer in one organ induces a resistance to the subsequent development of cancer in another organ would also explain another very curious fact which seems to have been overlooked by statisticians. There is a curious discrepancy between Holland and England in regard to the mortality from cancer of the breast and uterus: it is nearly twice as high for English women as for Dutch women. An international committee of distinguished statisticians working under the auspices of the League of Nations¹⁷ has undertaken to collect detailed statistics with the object of finding the reason for this remarkable difference. The report has just been published,¹⁸ and is a mine of valuable statistical information concerning cancer of the breast and uterus in these countries. But the committee has been unable to solve the problem.

Now though there is this great difference in the mortality from cancer of the breast and uterus between the two countries, there is no such difference in the total mortality from cancer. The mortality from cancer of all organs is, in fact, nearly the same in both countries, and if we investigate this point further we find that there is among Dutch women a much higher mortality from cancer of the stomach and intestine than among English women. The more frequent development of cancer in the intestinal tract among Dutch women protects them against the development of cancer in the breast. It might be equally or even more pertinent to inquire why Dutch women have a higher mortality from cancer of the stomach and intestine than why they have a lower mortality from cancer of the breast and uterus.

THE PARASITIC CONCEPTION.

An account of the essential features of the disease makes a very complex picture. The problem is to formulate a conception which will correlate, explain, and fit in with all the known facts and the truth of which can be demonstrated experimentally. All the numerous attempts to give an explanation of cancer can be conveniently divided into two groups: the parasitic conception and the biological conception. The parasitic conception explains cancer as being due to an extrinsic factor, the biological conception seeks to explain it by intrinsic factors—variations in the normal mechanism of cell life.

The attraction of the parasitic etiology of cancer is its simplicity. All we have to do is to find a micro-organism which is always associated with malignant new growth, and which, when introduced into the body, will by itself produce cancer as its specific disease, just as the *Spirochaeta pallida* produces syphilis and the tubercle bacillus tuberculosis. The experimental investigation of cancer has shown very clearly that the very simplicity of this conception makes it inadequate as a solution of the problem. I have already pointed out that the wide zoological distribution of the disease and its essential similarity in the different classes of animals would argue for one specific micro-organism as the cause. But if that were so, cancer should be transmissible from one species to another, which it is not. The strict limitation of the transmissibility of cancer, therefore, would argue for one specific micro-organism for each species, each micro-organism producing the same disease in each species. That seems highly improbable. But when we have conceded that, we are up against the difficulty mentioned before: we find that in transplanting a neoplasm from one animal to another of the same species we are not initiating the disease as we do in other diseases of known microbic origin, but we are merely keeping the cancer cells alive. That seems definitely to exclude the presence in a neoplasm of a micro-organism capable by itself of producing cancer. Nor can we explain in this way why a neoplasm grows out of its own resources and does not transform the surrounding tissues, why a carcinoma remains an epithelial growth and a sarcoma remains a connective tissue growth. From what I have said I think it is clear that the assumption of a specific micro-organism or even of an enormous group of specific micro-organisms which by themselves, when introduced into the body, produce cancer does not afford an explanation. It is for this reason that cancer researchers with rare

unanimity have in the past turned their back on the parasitic conception of cancer.

Now it may be argued that all these *a priori* considerations would fall to the ground as soon as one observer isolated a micro-organism specific for cancer in the sense that it is always present in malignant new growths and is capable by itself of producing malignant new growths experimentally in a sufficiently large number of experiments. The answer to that is that none of the claims put forward has withstood critical examination.

THE BIOLOGICAL CONCEPTION.

The second group of cancer theories are based on biological conceptions. We have here such theories as Cohnheim's view that cancer arises from embryonic rests, or Ribbert's hypothesis that dislocation of epithelium from its normal association with surrounding epithelium and connective tissue elicits latent powers of unlimited proliferation. These theories and a few others were elaborated before cancer could be investigated experimentally and before the technique of tissue culture *in vitro* had been developed. A detailed criticism of these various theories has been given in the second scientific report of the Imperial Cancer Research Fund. It is sufficient to say here that they do not explain all the features of cancer, and that when put to the experimental test they have failed.

Other biological conceptions have sought the solution of the cancer problem in a disturbance of the inner mechanism of the cell, especially that which presides over cell division. A vast amount of work on the cytology of the cancer cell has, however, failed to demonstrate any essential difference from the normal cell. The whole subject has been admirably summarized in a recent article by Dr. R. J. Ludford¹⁹ in the *Journal of the Royal Microscopical Society*. The biochemistry of the cancer cell has also been subjected to an exhaustive investigation and has been made the basis of many speculations.

So far I have tried to give you in rapid sketch an idea of the state of the cancer problem as it was six months ago. If it appears to you confused, that is exactly the impression which I wished to give you. The experimental investigation of cancer had brought to our knowledge a large number of facts concerning the disease. But many of these facts appeared to be so contradictory that it seemed impossible to correlate them by reference to a simple cause. As our knowledge increased the problem became more and more complex until we began to wonder whether what we call cancer was really a single disease and not perhaps a whole group of diseases each with a separate etiology.

THE WORK OF GYE AND BARNARD.

And now we come to "the last scene of this strange eventful history"—the work of Gye²⁰ and Barnard.²¹ Gye's conception of the etiology of cancer is that it is due to an ultramicroscopic virus common to different classes of animal. This virus when it enters into the cell stimulates it to the characteristic independent growth. But the mere presence of the virus in the body does not produce cancer, because by itself the virus is unable to attack a normal cell. In order to do this it requires the presence of an accessory factor or factors, which are furnished by the biological condition of the cell. This conception is a brilliant and ingenious compromise between the biological and the parasitic theories of cancer, and is in harmony with most of the essential features of the pathology of cancer.

But Dr. Gye did not develop his conception as the result of armchair speculation. It arose naturally from the results of a prolonged and technically very difficult experimental investigation on the peculiar fowl sarcomata discovered by Rous in 1911.²² These tumours, called "Rous tumours" for short, formed a particularly fascinating and puzzling chapter of cancer research. In a series of brilliant papers Rous disclosed the peculiar nature of these tumours. Little has been added to our knowledge concerning these tumours since. In fact, up to six months ago they had been neglected by cancer researchers as a disease which mimics cancer but is essentially different

* See BRITISH MEDICAL JOURNAL, January 23rd, p. 160.

from it. Now it appears that these tumours have in the hands of Dr. Gye furnished us with the key for the solution of the cancer problem.

These tumours have been observed only in fowls, and are rare even there. Histologically they are typical sarcomata, each possessing a very characteristic individual appearance. Rous described three such tumours: one was a spindle-celled sarcoma, the second was an osteochondrosarcoma, the third was a sarcoma having peculiar elongated rift-like blood spaces. Clinically they are highly malignant, growing with great rapidity and spreading very quickly throughout the body by metastases. On transplantation they retained their characteristic structure. Transplantation is limited not only to the same species but actually to one particular breed—the Plymouth Rock breed. In all these respects they behave, therefore, in the same way as typical malignant new growths. But they differ in one important feature: all other tumours, even other fowl tumours, could be transmitted only by using living tumour cells; when the cells were killed by any agency whatever the transplanted dead tissue failed to grow. This fact was always regarded as a strong argument against the parasitic theory of cancer. Now the Rous tumours can be transmitted by a saline extract which had been rendered completely free from cells by filtration through a Berkefeld filter. If the clear cell-free filtrate is injected, a new tumour forms rapidly. And the most astonishing thing is that the tumour formed by the cell-free filtrate retains its original structure. The filtrate from the osteochondrosarcoma forms an osteochondrosarcoma, the filtrate from the rifted sarcoma forms a rifted sarcoma.

Whatever the solution of this puzzling problem might be, one thing is clear—that these tumours can be transmitted by means of a "filterable agent," as Rous called it. *A priori* this might be either a chemical substance or a living filterable virus.

One of the first stages in Dr. Gye's work on these tumours was to determine which of these two alternatives was the correct one. He argued that if it was a virus it must be particulate, so that it can be brought down by spinning over a long time at a very high speed. He had found that when he incubated a piece of tumour anaerobically in broth of a certain composition the fluid in which the tumour had been circulated was capable of producing a tumour. By subjecting this fluid to spinning and injecting afterwards samples of the fluid separately from the top and from the bottom, where a slight deposit of the virus had been formed, he found that the top layer had become inactive, while the bottom layer rapidly produced a large tumour. The next stage was to decant after spinning the whole fluid from the deposit of virus, and after washing the deposit of the virus with saline to inject it into a chicken. He expected it to produce a tumour. What he found was—nothing! Nor did the top layer of the supernatant fluid produce a tumour. But when the washed virus was injected together with the supernatant fluid having the typical structure of the original sarcoma. Now an experiment of this kind shows very clearly that two factors are involved in the transmission of this particular tumour under experimental conditions: one is particulate—a virus; the other non-particulate—a chemical substance furnished by the tumour cells. The virus by itself is non-pathogenic. The second chemical factor enables it to enter the cells and then to stimulate them to the unrestricted, lawless growth characteristic of cancer cells. The chemical factor has a very specific action in so far as it renders only the same type of cell susceptible to the virus as that which composed the original tumour. Gye, therefore, calls this second agent "the specific factor," (speaking of the virus as the "extrinsic" factor, "intrinsic" to the cell), and of the chemical substance as the "intrinsic" factor, we see at once that this conception represents a compromise between the parasitic and the biological conceptions of cancer which have hitherto held the field as irreconcilable antagonists.

This conception is confirmed by a number of other experiments which I have no time to discuss. I may perhaps mention that the living nature of the virus has

been demonstrated both by the ultramicroscopic observations of Barnard and by experiments of repeated subculturing which demonstrated a multiplication of the virus.

So far as these experiments go they allow us to apply these conclusions only to these particular types of Rous tumours in the fowl. Can they be transferred to the tumours of mammals and of man? It is important to understand the fundamental difference between the transmission of these peculiar Rous sarcomata by a cell-free fluid and the transplantation of the majority of animal neoplasms by living cells. As I explained above, in transplanting a neoplasm by living cell we do not reproduce the disease in the new host *de novo*. The transplanted cells themselves continue to grow; the new host supplies the stroma and the food which enables the transplanted cells to live and grow. The tumour which forms is composed, not of the cells of the new host, but of the cells of the animal in which the neoplasm originated—possibly ten or twenty years ago. But when a Rous sarcoma is transmitted by a cell-free filtrate the connective tissue cells of the new host become malignant at the site of the inoculation, and we do reproduce the disease *de novo*.

What is the significance of this important difference? Does it mean that these Rous tumours are a disease *sui generis*, having an entirely different etiology from true sarcomata and only resembling them so closely as to mislead the unwary investigator? That was the view generally adopted, and the Rous tumours were considered to be not true sarcomata but infective granulomata. There had always been a difficulty in making a clear-cut distinction on histological grounds between these two groups of connective tissue tumours. The experimental trans- mission of these tumours seemed to furnish a definite criterion: tumours which could only be transmitted by living cells were true sarcomata, those which could be transmitted by a cell-free extract were infective granulomata.

But Gye refused to accept these definitions and decrees and for a decision appealed to further experimental evidence. And it is through taking this step that he has been able with his new technique to disclose the relationship between these Rous tumours of doubtful pedigree and the tumours of unquestioned cancerous origin, and thus to change completely our whole outlook on cancer. We have seen that the cells of the Rous tumours, but for the one exception, exhibit all the characters of a malignant cell: they invade the surrounding tissue, they form metastases, they retain their biological individuality both in the metastases and after transmission, they even show the narrow limitation of transmission within a species. Gye had found that in the Rous tumours these characters of malignancy are conferred upon normal cells of the new host when a virus is made to enter it by the presence of the specific factor. Now, he asked himself, if that is so, why should not the malignant character of the tumours of mammals and of men be due also to the presence of a virus in the tumour cells. How can this proposition be put to the experimental test? His answer was: By seeing whether the virus of the Rous tumour can be substituted by a virus from mammalian tumours, so that by adding the specific chemical factor from the Rous tumour to a virus from a mammalian tumour a sarcoma can again be produced in the chick. In practice the experiment is as follows: a piece of tumour from an animal or from man, as the case may be, is taken and incubated anaerobically under such conditions as would allow a virus to multiply free extract from a Rous tumour is treated in such a way as to remove or inactivate the virus, so that this fluid when injected into a chick also produces no result. Then both fluids are mixed and injected into a chick. If now a sarcoma arises the culture fluid from the mammalian tumour must have contained a virus.

In this way Dr. Gye has been able to demonstrate experimentally the presence of a virus in various sarcomata and carcinomata of the mouse and rat, and, so far as his published results go, in one human carcinoma. His conclusions based on such experiments have been confirmed by Mr. Barnard by the examination of Dr. Gye's cultures

by means of a new ultramicroscopic technique. By means of this technique Mr. Barnard has succeeded in studying the virus cultured by Dr. Gye, and he has been able to confirm its presence in those conditions in which experimentally a positive result was obtained.

VIRUS AND BIOLOGICAL FACTOR.

Dr. Gye's work, then, leads to the conclusion that the entrance into a normal cell of a specific virus confers upon the cells those characteristics which are the essential features of malignancy. The virus appears to be the same for a great many different classes of animal. The virus alone is, however, unable to effect an entrance into a normal cell. To do so it requires an accessory biological factor or factors. What these accessory biological factors are we do not as yet know: it may be a special functional condition of the cell, or the absence of oxygen, or an abnormal cell metabolite. Only in the case of the Rous tumours do we know for certain that the accessory biological factor is a chemical substance furnished by the tumour cells. But it does not seem to me to be an essential part of Gye's conception that the cells of every neoplasm must always produce such a substance. Once the virus has been enabled to enter into a few cells the trick is done and the cells are now impelled to grow. I wish to emphasize this point because some writers have quite arbitrarily made the demonstration of a specific factor in every neoplasm the touchstone of Gye's theory. The cells of the Rous sarcomata are exceptional in forming an abundance of such a substance, and it is this exceptional property which explains why the Rous sarcomata can be transmitted with a cell-free filtrate and why they have such a high degree of malignancy. If all sarcomata contained an abundance of this specific factor they could all be transmitted by a cell-free filtrate and they would all have the same highly malignant character. We know that this is not so. Further work will have to show whether different sarcomata vary in the amount or the stability of the specific factor formed by them. So far only one tumour—a mouse sarcoma—has been shown by Gye to be transmissible by a cell-free fluid, and in this case he found that the specific factor of this tumour was so sensitive to oxidation that its presence could be demonstrated only under very strict anaerobic conditions.

MICROBIC INFECTIONS AND ACCESSORY FACTORS— DEFENCE RUPTURE.

The conception that the virus of cancer by itself is non-pathogenic and can only elicit the disease if an accessory factor is present may at first appear too novel and unique to be readily acceptable. The orthodox teaching of bacteriology has, indeed, accustomed us to regard a disease of microbic origin as being the immediate result of the entrance of the microbe into the organism. That is so for many infections, but by no means for all. During the war it was generally recognized that though most wounds were infected with the bacteria of gas gangrene only a small percentage of the infected wounds developed gas gangrene. Dr. Gye and I were working on gas gangrene at the time, and being very much impressed by this fact we investigated the cause of this phenomenon. We found²² that if the bacteria of gas gangrene, or their spores, had by repeated washing been made completely free from all toxin they had become non-pathogenic and could be injected into animals in large doses without producing any effect whatever. But if a small amount of a soluble calcium salt was injected, not necessarily together with the bacteria but even when it was given several days afterwards and at a different site, gas gangrene developed at once and killed the animal. Dr. Gye informs me that on repeating the experiments a few years later with the washed spores of *Vibrio septique* he succeeded in producing gas gangrene by the injection of calcium salts six months after the injection of the spores. When the calcium salts were injected at a different site, the focus of infection was not where the bacteria had been injected but where the calcium salt had been injected. Further investigation showed that the calcium salt produced in the tissue a specific visible lesion of such a nature that

the normal defences of the subcutaneous tissues against the bacteria of gas gangrene were broken down and the bacteria could proliferate at the site of the lesion. We therefore called this phenomenon "kataphylaxis," or "defence rupture." We showed that the same holds true for tetanus and even for streptococcal infections. Other substances, strontium salts, some colloids, such as colloidal iron or colloidal silicic acid, have a similar effect. Gye and Kettle²³ showed that tuberculous infections could be induced in animals usually resistant to it by the injection of colloidal silicic acid. Orthodox bacteriology has taken no notice of this striking phenomenon; it is not even mentioned in the chapter on gas gangrene in the official medical history of the war.

These are infections occurring through the broken skin, and the onset of the disease is here determined by substances carried into the wound with the earth. Most ordinary infections take place mainly in the mucous membranes—namely, in the respiratory and the digestive tracts. These membranes are always in contact with bacteria, but are not ordinarily infected by them, because the secretion of mucus keeps the bacteria from coming into close contact with the tissues. Now one of the effects of a diet deficient in vitamin A is to produce an atrophy of the mucus-secreting cells.^{24 25} When this occurs the bacteria of the intestinal and respiratory tracts beginning in the mucous glands gain entrance into the blood stream. It is frequently stated that such a diet produces in the animal a general diminution in the resistance against infection. That, however, is not the case. These animals are no more susceptible to infection by bacteria injected subcutaneously than normal animals, nor do the usual serological tests show any deviation from the normal: it is a local diminution of resistance in specific tissues. Excessive radiation with radium produces a similar effect.²⁶ Here, then, we have two entirely different agencies—radiation and vitamin deficiency—eliciting accessory biological factors necessary for the bacterial infection of mucous membranes.

A very striking experiment bearing on this point has been recorded recently by Webster²⁷ of the Rockefeller Institute. He introduced mouse typhoid bacilli in equal doses into the stomach of mice. The mice were of the same strain, but were kept on two different diets. Both diets were adequate to keep the animals in good health and to enable them to breed, but one diet was so constructed as to be especially rich in vitamins. Of the animals kept on the vitamin-rich diet only 15 per cent. developed the disease and died. The mortality in the other group was 100 per cent.

All this goes to show that many microbic infections result not merely from the presence of the specific microbe but require accessory factors which vary with the different micro-organisms and the different tissues. To prevent a misunderstanding it may be stated that it is not suggested that the accessory factors just mentioned play any part in the production of cancer. There we have the various forms of chronic irritation which probably take their part in the etiology of cancer in this way. Directly or indirectly, they render cells susceptible to the entrance of the virus.

CONCLUSION.

It goes without saying that Gye's conception, in so far as it is based on experimental work, has to stand the test of experimental confirmation. What I have been trying to show is that his conception has given us a new outlook on cancer. Let us see now what his conception explains. The aimless, lawless, irresistible growth is the result of a virus entering into a few cells and impelling them to grow, freed from the control and inhibition which regulate the growth of the normal cell. The cell with the virus nevertheless retains its biological character as a cell of the species, of the tissue, and of the individual to which it belongs; hence the limitation in transmission and the fact that the cells of a neoplasm breed true. The virus is common to the tumours of different species and classes of animals; hence the wide zoological distribution of the disease. The virus by itself is non-pathogenic; that explains why the disease is not contagious. The virus can only enter a cell if some accessory biological factor is present: such a condition can be induced by very different forms of chronic irritation;

THE SURGICAL TREATMENT OF ANGINA PECTORIS.

BY

PROFESSOR D. DANIELOPOLU,

DIRECTOR OF THE SECOND MEDICAL CLINIC, UNIVERSITY OF BUCAREST.

In a previous article (BRITISH MEDICAL JOURNAL, 1924, ii, p. 553) I described my conception of the pathogenesis of angina pectoris, and of the mode of action of the sensory cardio-aortic nerve fibres in producing the attacks. I concluded that the best surgical operation applicable to this disease was the intercepting of the maximum number of the sensory cardio-aortic fibres without interference with the important groups of the cardiac accelerators. Jonnesco's operation, in which the stellate ganglion is removed, does

FIG. 1.—Course of the sensory cardio-aortic and of the cardiac accelerator fibres. The sensory cardio-aortic fibres originate in the heart and aorta and form two groups. The first group passes through the stellate ganglion and divides into: (1) a dorsal bundle, for the second, third, and fourth dorsal pairs; (2) a cervico-dorsal bundle, for the sixth, seventh, and eighth cervical, and first dorsal pairs; (3) a vertebral bundle, entering the fifth, sixth, and seventh cervical pairs through the cervical nerve; (4) the cervical sympathetic bundle, which unites the cervical and joins fibres reaching the trunk through the superior and middle cardiac nerves and the anastomoses which unite the cervical trunk, the vagus, and its branches. The cervical sympathetic bundle is divided between the first five cervical pairs, the medulla, and cranial nerves, and its branches. The group follows the cardiac branches of the Gasserian ganglion. It divides into: (1) a bundle without reaching the stellate ganglion, which originated from the first group; (2) a bundle following the superior cardiac fibres, and joining fibres in this bundle from the thoracic supply of the vagus. This bundle enters the vagus trunk and travels towards the medulla, a part of it traversing the anastomoses in the cervical bundle.

not fulfil these conditions, and should be abandoned for the following reasons.

1. The Jonnesco method intercepts important groups of the cardiac accelerator fibres, and the coronary and pulmonary vasomotor nerves. Physiologists have shown experimentally that animals deprived of their extracardiac nerves lose the power of resistance, and it has also been proved that removal of the stellate ganglion weakens the heart beat. By repeating such tests in dogs I have found that excision of the first thoracic ganglia seriously affects the fundamental physiology of the myocardium. The alterations are rendered still more grave if this operation is preceded by ligation of certain branches of the left coronary artery.

hence the local origin of the disease. We can also understand why agencies so different as tar, x rays, and animal parasites are capable of inducing cancer. Under exceptional conditions the parenchyma of a carcinoma may have such an effect on the cells of its stroma that the virus is able to infect the connective tissue cells and a sarcoma arises from a carcinoma. The cells of some very rapidly growing and highly malignant tumours produce in abundance a substance which will act as an accessory biological factor, but only for the same type of cell as the one of which the tumour is composed. Such a tumour can therefore be transmitted by a cell-free filtrate containing both virus and the specific factor. Other tumours contain less of this specific factor or it is more labile; they can therefore only be transmitted by living cells. There is therefore only a fundamental distinction between these two types of neoplasms, as was hitherto supposed; they differ only in degree. These differences in the amount of specific factor present in the clinical behaviour of different neoplasms as regards rate of growth and malignancy. A tumour forming an abundance of the specific factor will grow rapidly and metastasize rapidly, because in such an extreme case the tumour will grow, not only by cell division, but also by a transformation of the normal cell of the same type. This would explain the fulminating growth of some types of cancer in the human subject. Tumours containing less of this specific factor or forming a less stable specific factor will grow more slowly and metastasize less rapidly. The striking fact that the growth of a neoplasm is independent of the nutrition of the animal in which it grows calls, as we have seen, for an explanation which places the impetus to grow within the cancer cell. This is obviously in accord with the conception that the growth of a cancer cell is due to an intracellular virus assisted by a chemical factor elaborated by the tumour cells.

Gye's work raises many new problems into which I cannot now enter, but it has solved our old and fundamental difficulties. Its particular merit is that it is not in conflict with any of the previously established facts, but, on the contrary, it confirms them. Taking them as his starting point, he has just gone one step further, and in doing so he has hit upon a conception which links together all our knowledge concerning cancer, which removes all the apparent contradictions, and which, so far as I am able to judge, explains all the essential features of the disease. It is the first adequate explanation of the causation and growth of cancer, and it points the way to further progress.

2. Removal of the stellate ganglion by the Jonnesco method has produced high mortality in Basedow's disease and in epilepsy (about 20 per cent. in each). In his text-book published in 1923 Jonnesco states that only one of 130 cases of epilepsy treated by his operation proved fatal. Brunning, however, has remarked that the statement is not consistent with one made in 1899, when Jonnesco stated, in Braun's thesis, that 8 out of 33 cases had been fatal. In epilepsy death occurred immediately after the operation or followed it within one, fifteen, or seventy days. Many of the rather numerous fatal cases occurring in Basedow's disease after removal of the stellate ganglion were preceded

FIG. 2.—Cardio-vascular reflexes in angina pectoris. Sensory pressor and depressor fibres emerge from the heart and aorta. The depressor fibres pass to the medulla: (1) to the moderating vagal centre—slowing of the heart by the depressor reflex is thus explained; (2) to the vaso-dilator centre, which is in turn in relation with vaso-dilator centres in the lower part of the dorsal cord; these facts explain the abdominal vaso-dilatation and fall in blood pressure produced in the depressor reflex. The indirect connexions between the sensory depressor fibres and the vaso-dilator centres of the peripheral circulation are not shown; these are also concerned in reducing the blood pressure (François Franck). The pressor fibres are connected with centres in the medulla and cord: (1) with the medulla accelerator centre in relation, through descending fibres, with accelerator centres in the lateral horns of the cervico-dorsal cord. These connexions explain the cardiac acceleration accompanying the pressor reflex; (2) with the medullary vaso-constrictor centre, connected by descending fibres with the centres in the lower part of the dorsal cord. The pressor reflex thus causes abdominal vaso-constriction and increases blood pressure. But other pressor fibres exist, not traversing the medulla and directly influencing the medullary vasomotor centres through sensory fibres which reach the cervico-dorsal cord through the inferior cardiac nerves and stellate ganglion. These fibres affect: (1) vaso-constrictor and vaso-dilator centres of the upper limbs, which explains the modifications in the brachial pletysmogram described by me in angina; (2) vaso-constrictor centres in the lower part of the dorsal cord reached by descending fibres; thus is explained the rise in blood pressure produced in dogs by stimulating the central end of the Viessens loop; (3) accelerator centres in the medulla. Different sensory cardio-aortic fibres reaching the medulla and cord may possibly affect the motility of the coronary vessels, as well as that of the pulmonary vessels. These connexions show that all stimuli starting from the heart and aorta travel centrifugally by way of the sympathetic as well as the parasympathetic. Normally the parasympathetic group is the more affected, explaining the depressor reflex produced by stimulation of the heart and aorta. In angina pectoris the sympathetic fibres are more affected, the depressor reflex being thus absent, and the pressor present. Reflexes starting from the heart and affecting the vessels are more marked on the left side, for the following reasons: (1) The cardiac nerves are more developed on this side. (2) The myocardial pressure producing the anginal attacks, or which in other abdominal states give rise to different vascular reflexes, occurs most intensely in the left ventricle, which is more related with these states and possesses the largest amount of cardiac muscle. This mechanism explains why anginal sensations and disturbances which occur in various abnormalities of the heart are situated on and radiate especially toward the left side. (3) Coronary lesions are more marked on the left side. Myocardial sclerosis so produced renders the left sensory terminations hypersensitive, a factor predisposing to anginal attacks.

by signs of myocardial insufficiency. The mortality would prove to be much higher if the cases were followed up for longer periods, and if all the fatal cases were published.

3. The mortality of the Jonnesco operation in angina pectoris is also high. In one case death occurred four days after the operation, with signs of acute asystole of the left heart, and with pulmonary oedema; in a second case death followed similarly in four days. In another case the patient was found dead in his bed the day after the operation. In a case in which Hofer applied the Jonnesco operation the patient died within twenty-four hours, with pulmonary oedema and asystole of the left side of the heart. A case treated by Diez ended fatally in a month, one by Radici

in twenty-one days, and one by Reid and Friedländer in fifteen days. Arrilaga reported recently a case of death with syncope phenomena after this operation. Most of these patients presented signs of acute myocardial insufficiency, which shows the danger of dividing cardiac accelerators in a disease in which the myocardium is so often much degenerated. Again, Arrilaga has shown that the Q.R.S. phase, as indicated by the electro-cardiogram, becomes prolonged in anginal cases after excision of the stellate ganglion by the Jonnesco method; a fact which indicates aggravation of the myocardial condition. Diez confirms the findings of Arrilaga, who also, with Clerc and Basconnet, insists on the gravity of this change. In cases where it occurred, 60 per cent. of the patients died during the year. When an anginal subject, who has never presented

FIG. 3.—Path through which pain radiates in angina.

the signs of asystole of the left side of the heart, shows this syndrome and dies on the day of operation or soon after, and when we remember that the positive inotropic function of the accelerator fibres is intercepted by the Jonnesco treatment, these untoward results must inevitably be attributed to the removal of the stellate ganglion.

4. Cases of survival after the Jonnesco operation may be explained on the assumption that the myocardium has not degenerated to the same extent in all anginal cases. It is also true that most of the cases so far reported have not been followed up for a sufficient length of time. We do not know how long we must wait to be sure that interception of the accelerators has not injured the myocardium. Such reports are incomplete, the only really complete cases being the fatal ones. Surviving patients should not figure in the statistics unless operating surgeons report the clinical conditions existing some years after operation. I may also remark that excision of the stellate ganglion is a rather difficult technical procedure. In the hands of a surgeon so experienced as Jonnesco complete excision may be counted upon, but I seriously doubt whether it has been complete in all the cases operated upon for angina by those operating thus for the first time. Such incomplete excision may also explain the survival of some cases, as compared with the particularly high mortality reported by Jonnesco.

Most reports on the Jonnesco operation are made by surgeons; no cardiologists have yet accepted it, and the question is one for cardiologists. I was the first to point out the danger of removing the stellate ganglion; but Wenckebach is of the same opinion and suggests section of the depressors, while Hofer also has condemned the Jonnesco operation. Diez, who at first approved the operation, has now written to me supporting my view of it, since in one of his cases sudden death occurred one month after the operation. In his important work on the heart Vaguez is inclined to approve my treatment, which leaves the stellate ganglion untouched, and Richon concurs, maintaining that extensive mutilation of the ganglia endangers the centrifugal fibres. Leriche categorically opposes the Jonnesco operation, as it was followed in four cases by death from acute asystole of the left side of the heart.

PERSONAL METHODS.

In 1922 I remarked that removal of the stellate ganglion should be abandoned, but that I hoped that angina pectoris

might be improved by cutting other nerve fibres, and I suggested section of the cervical sympathetic. Clinical and experimental studies made then have enabled me to add during the last three years the division of other nerves without danger and probably with benefit. The procedure which has gradually evolved is as follows:

1. Section of the cervical sympathetic (Fig. 5). We thought at first that section of the cervical sympathetic was necessary; we also contemplated altering the connexion of the visceral sensory neuron with the cerebro-spinal sensory neuron situated in the cord or spinal ganglion by dividing, or blocking with alcohol, the second, third, and fourth spinal nerves. Since fresh experiments were necessary, and are now progressing, discussion of this point must be postponed. Section of the cervical sympathetic was successfully accomplished by C. F. and A. F. Jennings in 1924. In the previous year Coffey and Brown had combined section of the cervical bundle with division of the first cardiac nerve. The five cases thus treated were clearly improved.
2. Section of the cervical sympathetic and vertebral nerve, or section of the anastomoses connecting the superior cervical ganglion with the cranial nerves (Fig. 6). The vertebral nerve may contain sensory fibres; its section is therefore desirable. Gino Pieri de Belluno tried my method of dividing the cervical bundle and the vertebral nerve; improvement followed. In my previous article in this JOURNAL I advocated that in addition to cutting the cervical

My method is wholly different from that of Jonnesco, who claims that sympathectomy is ineffective unless the stellate ganglion is included, as practised by him in epilepsy and Basedow's disease. My method is based on the following data:

1. My clinical and experimental studies have shown that all the nerves selected for section contained sensory cardio-aortic fibres. Radiation of pain to the lower jaw and the palatine vault showed that the cervical sympathetic is partly sensory. Radiation of pain to the pathway of the cervical pairs of nerves indicates that section of the rami communicantes, which unite the cervical cord, intercepts many sensory fibres. Radiation of pain to the path of the eighth cervical and first dorsal nerves proves that sensory fibres exist in the communicating branches which I propose to divide. Results obtained in dogs show that the vertebral nerve sometimes contains sensory fibres, and may be cut with advantage. Hofer's operation, which proved that cases improved after division of some branches of the vagus, indicates that this nerve contains sensory fibres. I believe that all intrathoracic branches of the cervical vagus should

FIG. 4.—Cervico-thoracic sympathectomy: the Jonnesco method. Removal of the entire cervical chain and of the first thoracic ganglion. The operation leaves intact the sensory cardio-aortic fibres contained in the vagal branches, and interrupts highly important accelerator fibres and coronary and pulmonary vasomotor fibres, causing fatal results.

FIG. 5.—Section of the cervical sympathetic. (Danielopolu and Iristide Soc roumaine de biol., November 2nd, 1922.)

FIG. 6.—Section of the vertebral and cervical sympathetic, or section of the anastomoses connecting the superior cervical ganglion to the cranial nerves. (Danielopolu, January, 1924)

FIGS. 7 AND 8.—Resection of the inferior cervical and first thoracic ganglia, with or without section of the vagus (October, 1924). Fig. 7 represents the more complete, operation. Fig. 8 represents the less complete, operation.

FIG. 9.—Resection of the cervical sympathetic chain, leaving the inferior cervical and first thoracic ganglia intact, with section of the inferior nerve, of branches of the vagus, and of vagal branches entering into the thorax; and of communicating branches uniting the inferior cervical and first dorsal pairs; and section of the fibres occasionally passing from the superior laryngeal to the vagus. (Danielopolu, February 4th, 1925.)

sympathetic and the vertebral nerve, those fibres should also be divided which were widely distributed within the thorax from the cervical sympathetic and cervical portion of the vagus.

3. Resection of the cervical sympathetic chain (leaving the inferior cervical ganglion intact) with section of the vertebral nerve and of all vagal fibres descending into the thorax (Figs. 7 and 8). If some of these nerves are absent or are too difficult to divide, the operation described is feasible should be made, but in all cases the cervical sympathetic should be excised. After suggesting the existence of numerous anastomoses between the cervical sympathetic and the vagus and its branches, which probably contain sensory cardio-aortic fibres. Apart from the inferior ganglion, which is left intact in this operation, the cervical sympathetic contains no important groups of cardiac accelerator fibres, and may therefore be removed, in accordance with the principle of dividing as many as possible, of the important sensory fibres, with the least possible interference with the principle of my recommendation to remove the stellate ganglion intact, published results obtained in three cases of angina pectoris in which he had removed the cervical sympathetic without interfering with the inferior ganglion—the operation advocated by me in 1924. His results were excellent.
4. Resection of the cervical sympathetic (leaving the inferior cervical ganglion intact) with section of fibres of the cervical vagus and its intrathoracic branches; section of the vertebral nerve and section of communicating branches uniting the inferior cervical and first thoracic nerve with the sixth, seventh, and eighth cervical and first dorsal nerves (Fig. 9). If a nerve is present which connects the superior laryngeal and the vagus, it must also be cut; the operation must be as complete as possible, and any inaccessible nerves must be left. Jacobovici reports a case of angina in which my method proved highly successful; Leriche had similarly favourable results in one case. I have made this last method as perfect as possible because my experiments had shown the value of dividing various nerves the section of which was harmless. In all my experiments I have observed the principle of cutting as many of the sensory cardio-aortic fibres as possible, without touching the important cardiac accelerator fibres which pass through the stellate ganglion.

be divided. My dissections have brought to light numerous anastomoses between the vagus, the sympathetic, and their branches, the various fibres probably meeting at these anastomoses. Since we must not divide the vagal trunk, we have everything to gain by removing the cervical sympathetic (except the inferior cervical ganglion), and thus intercepting the sensory fibres in the anastomoses and communicating branches.

2. My experiments have also shown that the nerves selected for section contain no important cardiac accelerator fibres, which exist chiefly in the communicating branches from the second, third, and fourth dorsal nerves. I have not found any accelerator fibres in the communicating branches uniting the stellate ganglion with the last cervical pairs of nerves and the first dorsal nerve. In experiments on dogs it was found that the vertebral nerve contained no important accelerator fibres.

3. I have also determined the presence of sensory fibres in the second, third, and fourth communicating branches. These nerves, however, must be preserved, since they contain cardiac accelerator fibres. My investigation has also proved, as previously reported, that angina pectoris may be much relieved, even though all the sensory cardio-aortic fibres are not divided. While leaving intact the important nerves, such as the vagal branches, which contain many sensory cardio-aortic fibres. Relapses occurring after the Jonnesco operation are due to the fact that this method leaves the vagal branches intact.
4. Though not a surgeon, my study of the cadaver has shown that these various nerves may be usually divided or resected; moreover, Leriche has stimulated these nerves

during operations on man. My method is also easier than that of Jonnesco, in which the excision of the stellate ganglion requires expert skill.

Such are the arguments in favour of my method. The probability that it will be very effective is indicated by the improvement obtained by Hofer's operation, which divides the depressor nerve, and the results of my earlier methods, including cervical sympathectomy and section of the sympathetic and vertebral nerves. In the report of the Nancy Congress (*Presse Méd.*, August, 1925) occurs this note: "Leriche of Strasbourg reports a case of angina pectoris without cardiac lesions but accompanied by slight aortic dilatation, which has remained cured for five months thus far, by removal, after the principles stated by Daniélopou, of the left cervical sympathetic chain, from the upper cervical to the stellate ganglion, which was left intact. The last three cervical communicating branches and the two roots of the vertebral nerve were also divided. The result is excellent." Jacobovici also obtained a good result in one case by applying my method. The earlier operations in which my method was used were thus very encouraging. As to the question of danger, all the clinical and physiological facts permit me to state that the nerve interferences are harmless. The fatal results after the Jonnesco operation are due to acute myocardial insufficiency produced by removal of the stellate ganglion, which I leave untouched. The question may be raised whether the operation should be performed bilaterally. I have always believed that operations on the sympathetic should be as conservative as possible. The operation should be completed on the left side, and supplementary operation on the right side performed only if the first treatment proves insufficient.

SUMMARY.

In the Jonnesco method the division of certain nerves, such as the cardiac accelerator fibres, involves danger, while nerves which may be divided usefully and without injury are left untouched. By my method it is the former which are left intact, and many nerves—possibly more than in the Jonnesco operation—which contain sensory cardio-aortic fibres, are severed. In order to judge the value of the Jonnesco operation the cases, which are now sufficiently numerous, should be followed up for several years. It is not prudent to continue this operation, which has been followed by fatal results, before trying a method which appears to be wholly harmless and probably very effective. My operation has its contraindications: it should not be employed if signs of myocardial insufficiency are present. Thus, for example, I do not advise it when anginal attacks are complicated by pulmonary oedema, which indicates the presence of extensive myocardial degeneration. Even so Jonnesco's operation would appear to be much more dangerous than mine in these cases. The number of methods which I advise may seem surprising, but the methods are successive, each one perfecting a preceding one. Some proved excellent from the first, but in each new operation division of more sensory cardio-aortic fibres has been attempted in order to make the benefit more complete. The operation should, however, be as complete as possible in each case, resection of the cervical sympathetic being supplemented by section of the vertebral nerve and the communicating branches mentioned, and of certain branches of the vagus, in so far as anatomical peculiarities or technical difficulties allow. Cervical sympathectomy alone is sometimes very effective, but even this may sometimes be impossible because of the general condition of the patient. In such cases treatment should include simple section of the cervical sympathetic bundle, with or without section of the vertebral nerve, intrathoracic branches of the vagus, and the communicating rami. The number of sensory cardio-aortic fibres will be reduced and the pressor reflex, which is the primary cause of the anginal attacks, will be diminished. When clinical improvement has started the operation may be completed at a later date.

In addition to the classical angina pectoris, surgical treatment may be considered in abdominal angina. Some of these cases are only angina pectoris with an unusual pain distribution, and may be relieved by the surgical treatment applicable to ordinary angina pectoris; in other

cases, however, a real abdominal syndrome exists, due to arteritis or atheroma in the abdominal aorta, the coeliac trunk, or the gastro-intestinal arteries. Here the syndrome is referable chiefly to sensory fibres supplying the abdominal viscera. To prevent the attacks in such cases the solar plexus must be treated.

The practical conclusion appears that surgical treatment of angina pectoris is of general application. Cases must be well selected, and the completeness of the operation will depend upon the patient's condition. I cannot, therefore, agree with Mackenzie, who has stated that anginal patients should never be treated surgically. The Jonnesco method involving the removal of the stellate ganglion may perhaps be abandoned, but the method I suggest is far more hopeful, and offers much promise in practice.

NOTE.—While this article was in the press there appeared Fontaine's thesis, *Traitement chirurgical de l'angine de poitrine* (édition universitaire de Strasbourg). In this thesis, inspired by Professor Leriche, Fontaine has collected 100 instances of angina pectoris treated surgically, and reaches the following conclusions. He agrees with me in condemning Jonnesco's operation, which leads to acute cardiac failure with death, owing to the removal of the stellate ganglia. Fontaine cites numerous fatal cases, and a note by Leriche on a case in which excision of the stellate ganglia for paroxysmal tachycardia provoked acute asystole. An additional reason for abandoning Jonnesco's operation is, according to Fontaine, that the methods in which the stellate ganglia are not touched have proved so much more effective.

A CASE OF ABDOMINAL TORSION OF THE OMENTUM.

BY

FRANCIS R. BROWN, O.B.E., F.R.C.S. Ed.,
ASSISTANT SURGEON, ROYAL INFIRMARY, DUNDEE.

In the introduction to his paper on abdominal torsion of the omentum Mr. Ernest Cowell¹ writes:

"Abdominal torsion of the great omentum, unaccompanied by complications arising from, or factors associated with, any form of hernia, is a rare condition. A search of the literature from 1882 to the end of 1924 has revealed only eighteen recorded cases, including a new case met with in the surgical practice of the author. In view of the fact that few surgeons publish isolated cases, especially in this country, it is hard to believe the condition is really as rare as one might otherwise suppose. Of the 18 cases, 8 are reported from America, 3 from Germany, 2 from Austria, 2 from France, 1 from Australia, and 2 from England. Torsion of the great omentum associated with hernia is not uncommon. Considerably over a hundred papers have been published on this subject, and approximately 140 cases described."

Since meeting with the case here reported I have heard of no fewer than three apparently similar cases, none of which, so far as I am aware, has as yet been published. The condition, therefore, as Cowell suggests, is probably not as rare as would appear from the scanty literature.

A man, aged 63, was admitted to Dundee Royal Infirmary on November 23rd, 1925, complaining of pain in the right side of the abdomen of four days' duration. Since boyhood he had worked as a colour mixer in linoleum works—lead colours being used. The pain came on gradually, steadily became worse, and was aggravated by coughing or taking a deep breath. There was no vomiting, and the bowels, always regular, had moved daily since the onset. He was of average build, and rather thin. General condition good. He complained of pain in the right iliac fossa. Temperature 97.2°, pulse 72. Abdomen slightly distended; no respiratory movement in lower half. Liver dullness normal; flanks clear. Resistance all over the abdomen with "boarding" on the right side extending from the right iliac fossa almost to the costal margin. There was definite acute tenderness over the area of "boarding." No palpable swelling, and no hernia. Rectal examination negative. Leucocyte count, 15,200 per c.mm. Tongue dry, and slightly furred. Lower teeth carious with advanced pyorrhoea. A pre-operative diagnosis of appendicitis was made,

although it was recognized that the clinical features were not altogether indicative of that condition.

Operation.

The abdomen was opened by a right paramedian incision, the rectus muscle being displaced outwards. The appendix was normal. A dark red mass, measuring $3\frac{1}{2}$ by 1 $\frac{1}{2}$ inches, was found adhering by its lower extremity to the middle of the ascending colon. This was easily separated, and proved to be an isolated (or accessory) portion of omentum attached by a twisted pedicle directly to the transverse colon, and well to the right of the main organ. It was found impossible to untwist the pedicle owing to an elastic recoil which at once reproduced the original torsion, thus demonstrating that the anchoring of the mass by its lower end to the ascending colon was not essential to maintain the torsion. The twist, of two complete turns, commenced about half an inch distal to the colic attachment, so that it was a simple matter to ligature the pedicle close to the transverse colon and remove the mass. Appendicectomy was performed, and the abdomen closed. The patient made an uneventful recovery, and was discharged on December 8th.

In the eighteen cases collected by Cowell the ages ranged from 14 to 55; this case is therefore the oldest on record.

In considering such an apparently rare condition as abdominal torsion of the great omentum one wonders whether any (or many) such cases have been missed through the use of a gridiron incision to open the abdomen.

For the accompanying illustration my thanks are due to Dr. W. O. Reid, Dundee.

A METHOD OF ESTIMATING THE SIZE OF AN ENLARGED PROSTATE.

BY

P. CLENNELL FENWICK, C.M.G., M.D., F.R.C.S.ED.,
OFFICER IN CHARGE, RADIUM DEPARTMENT, NORTH CANTERBURY
HOSPITAL BOARD, CHRISTCHURCH, NEW ZEALAND.

It is always difficult to estimate the size of an enlarged prostate, and the usual method of recording this by comparison with the size of a tennis ball, apple, or other object is unsatisfactory. To note that the prostate is enlarged to the size of a large apple does not help one at a subsequent examination, and if the case is referred to another surgeon this note is of no value, depending as it does on the personal opinion of the first examiner, whose idea of a large apple may differ from that of the next person to examine the patient. In order to make some sort of accurate measurement I have been using the following device, which, if not scientifically exact, at least gives definite figures which can be checked at any future examination.

The three measurements I wish to obtain are: (1) the width—that is, the distance from side to side; (2) the vertical—the distance between the upper and lower edges; (3) the thickness—that is, the distance between the floor of the prostatic urethra and the rectal wall.

FIG. 1.

by the finger to the left lateral limit of the gland, as represented by the line n-c (Fig. 1). An assistant holds a sheet of cardboard resting against the back of the patient's thighs, and marks with a pencil the position of the end of the probe (c). The finger then moves the probe across the gland to the right lateral limit of the swelling, and the new position of the end of the probe is marked on the cardboard (d-e). With the nail of my right forefinger I mark the point where the probe enters

the anus, and withdraw the probe. Laying the probe on the cardboard, and measuring the distance between the points e and c, I can obtain the distance between the points a and b, which I record as the width of the prostate.

To measure the vertical length a piece of drainage tube 20 cm. long is slipped over the probe and pushed up to the point (Fig. 2). The left forefinger is passed into the rectum, and the probe with its rubber cover introduced along the palmar surface, and pushed up until the finger reaches the upper limit of the gland. Keeping the probe in this position, the rubber cover is gently pulled down by the right hand until the lower margin of the gland is reached. The rubber and probe are then pinched together and removed. The uncovered end of the probe is measured, and this gives the vertical length of the gland.

FIG. 2.

To measure the distance between the floor of the prostatic urethra and the rectal wall I use a rigid rubber-covered probe (Fig. 3, A) soldered at right angles to a 10 cm. rule (B). A brass block (C) 2 cm. square and 4 cm. long is slotted to slide along the rule, and is drilled at the upper end to form a sleeve fit for a catheter (X). A circular window (Y) is drilled in the centre of the block to serve as a window through which the scale can be read.

FIG. 3.

The catheter is passed gently into the bladder until urine flows. The rectal tube is passed into the rectum and pressed against the prostate. An assistant then very gently slips the end of the catheter into the hole in the brass block and slides the block backward towards the rectal probe until the tissues prevent further movement. As the catheter and probe are rigid and parallel the thickness of the gland is shown by the point on the scale that is seen through the window. An x-ray photograph taken with the patient lying on his side with the instrument in position showed the lines of the rectal probe and catheter to be quite parallel.

The three measurements are recorded in my notes. I take some dental wax and mould it into the shape given by the measurements, adding any irregularity or abnormality discovered by the examining finger. The model is labelled with the patient's name, and serves as a record of the examination.

While not suggesting that this method is ideal, I may claim that it is painless and gives some fixed figures to record.

OPERATIVE TREATMENT OF ACUTE PERFORATED ULCER OF THE STOMACH AND DUODENUM:

OBSERVATIONS ON SIXTY-SEVEN CASES.

BY

ARTHUR J. EVANS, F.R.C.S.ED.,
SURGEON, STANLEY HOSPITAL AND BROWNLOW HILL INFIRMARY, LIVERPOOL;
LECTURER IN CLINICAL SURGERY, UNIVERSITY OF LIVERPOOL.

It is generally admitted that duodenal ulcer, like appendicitis, is markedly on the increase, and that the complication of perforation is now common. In patients suffering from duodenal or gastric ulcer perforation is said to occur in 28 per cent. of male patients and in 9 per cent. of female.¹ Spontaneous recovery occurs only occasionally; I have seen only one such case, upon whom it was necessary, some months later, to operate for pelvic abscess and a recrudescence of the symptoms of ulcer. Perforation is often a "seasonal" complication: it occurs with greater frequency during the

winter months, and more especially during the lessened vitality which is generally associated with the later months of winter. During the month of December, 1924, I had under my care in my own wards at the same time no fewer than 10 cases of perforated duodenal ulcer.

During the past fifteen years I have operated on 64 cases of perforated duodenal and pyloric ulcer and 3 of gastric perforation. A number of duodenal cases have been of the juxtapyloric variety, the ulcer and surrounding induration invading both the pylorus and duodenum. All these cases have been in males, and all have been ulcers of the "chronic" variety, with sudden perforation into the free abdominal cavity. In 53 the perforation occurred on the anterior wall of the first part of the duodenum or pylorus; one on the posterior wall of the duodenum. In 10 the site was the upper surface of the pylorus or duodenal "cap," and in 3 the lesser curvature of the stomach.

It is a surgical platitude to insist that success in treatment depends on early diagnosis. The practitioner who recognizes this serious condition at once deserves more credit for his patient's recovery than the surgeon who operates. The object of this paper is to discuss the fundamental principles of surgical procedure, about which, at the present time, there is so much controversy.

My first 7 cases (1910-11) were dealt with by simple suture of the perforation, with the usual drainage of the site of perforation and pelvis. Of these 5 recovered and 2 died (a mortality of 28 per cent.); the interval between perforation and operation varied from four to thirty-eight hours. Of the 2 who succumbed, in one the perforation had occurred thirty-two hours and in the other thirty-six hours before operation. Of the 5 recoveries 2 returned with recurring symptoms of ulcer, and were later dealt with by gastro-enterostomy. My eighth case, dealt with by simple suture, was complicated a few days later by leakage at the site of perforation, with the appearance of bile and gastric juice through the wound. The perforation was then again closed, and posterior gastro-enterostomy performed. The rapidity of this patient's recovery was so striking that in my next case I was led to undertake the combined operation, with a most successful result.

The number of cases since operated upon has been 59; 2 were treated by simple suture and 57 by suture and gastro-enterostomy. The latter cases represented almost every grade of perforation, with intervals varying from two to thirty hours following perforation. The age of the patients ranged from 18 to 60. Among the last 12 cases there was only one death, which followed three weeks after operation owing to deficient drainage.

TABLE I.—Summary of Results.

	Cases.	Recovered.	Died.	Mortality per cent.
Simple suture... ..	9	6	3	33½
Suture and gastro-enterostomy...	58	45	12	20

Total mortality of 67 cases = 22 per cent.

Assuming that the condition of the patient will warrant such a procedure, the question of gastro-enterostomy in these circumstances usually depends on the period which has elapsed since perforation; the age, sex, and general health of the patient; and last, but not least, the immediate facilities for undertaking such an operation. Deaver and Pfeiffer² have recently published a similar number of cases, performing the combined operation in 45, with the loss of only 3, while Mr. G. P. Mills³ has also published a series of 22, with a mortality of 4.5 per cent. A study of the records of my own cases, and of others, has led me during the past few years to perform the combined operation as often as possible.

The early complications which may arise after simple suture are: leakage at the site of perforation some days after the operation; haemorrhage from the ulcer; perforation of a second ulcer; persistent vomiting, from the narrowing of the pylorus or duodenum. The remote complications are: frequent recurrence of symptoms of ulcer with possible reperforation, in addition to the diffi-

culties encountered in a possible second operation; from adhesions, etc.

Immediate gastro-enterostomy has certainly, in my experience, reduced the mortality. The combined operation does not entail any increased risk to the patient. It represents an additional fifteen or twenty minutes under the anaesthetic, but this is more than counterbalanced by its immediate advantages.

1. The operator can boldly and efficiently infold the perforated area, without risk of subsequent stenosis at the gastric outlet or leakage at the point of closure.

2. Fluids can be given by the mouth almost immediately after recovery from the anaesthetic.

3. The peristaltic movements of the intestine can be earlier stimulated by the administration of purgatives; thus counteracting the distension of the intestine due to partial paralysis.

4. A more rapid and efficient drainage of the peritoneal cavity by an early action of the bowels is produced; this, I consider, is one of the most important advantages. These points have been well brought out by H. J. Paterson.⁴

Complications.

The cause of failure in a considerable number of my cases has not been immediate shock, but either subsequent bronchopneumonia or a subphrenic or residual abscess. Protection of the patient, both during and after operation, has been followed by marked improvement in respect of the first complication, and there have been no deaths from it in the last 15 cases.

The question of drainage is still a debated point—the tendency is to drain less. Complete closure of the abdomen after perforation is a very uncertain "surgical gamble"; it is impossible to forecast whether complications will ensue or not. I have lost one case through deficient drainage, and strongly urge that the pelvis, at least, should be drained in all cases in which perforation has occurred more than two hours before operation.

The Operation.

I have found the perforation is most securely closed by a double row of interrupted fine silk sutures; an initial purse-string suture often causes trouble—it will cut through the friable indurated and oedematous tissue, and so enlarge the perforation. Catgut is liable to digestive action, when leakage ensues. Simple dry mopping of the soiled abdomen is resorted to, and the posterior gastro-enterostomy performed in the usual way; a suprapubic "stab" wound is then made, and a drainage tube passed down into the pelvis.

After-History.

It was difficult to follow these patients up, but I have seen all of them from time to time—some a few months and some many years after operation. I have not been called upon to deal with any complication beyond ventral hernia on one occasion. The majority appear to have been entirely cured. Some have complained of symptoms obviously due to adhesions, the inevitable result of severe peritonitis. It must be realized that if gastro-enterostomy is performed for uncomplicated ulcer or for its perforation the process of physiological digestion has been profoundly altered. The patient should be warned of this, and his diet and habits regulated to meet the new conditions; this is well emphasized by Sir Berkeley Moynihan.⁵

I have read with great interest the recent criticisms of the combined operation, and especially those of Mr. Zachary Cope,⁶ whose judgement and experience I have reason greatly to respect. The method adopted in dealing with the cases here recorded was not influenced by the results of others, but rather by my own personal experience as time went on; it appeared to me that the anastomosis helped, in very large measure, the recuperative powers of the patient—first by "indirect" drainage and elimination, and secondly by the early administration of fluids by the mouth, with no danger of subsequent leakage through the diseased and friable perforated area. It is easy to allow enthusiasm to warp judgement, and it is possible that my mortality percentage might have been lowered by restraint.

As time went on, however, results improved. Table II contains an analysis of the cases dealt with during the last six months of the year 1924, drawn up by my house-surgeons, Dr. J. I. Noble and Dr. W. F. Jones, at the Liverpool Stanley Hospital and Brownlow Hill Infirmary. The cases were treated by combined suture and gastro-enterostomy; 11 made uneventful recoveries, 1 died three weeks after operation from residual abdominal abscess; all were of the male sex.

TABLE II.—Analysis of 12 Cases Operated on during the last Six Months.

Age.	Hours between Perforation and Operation.	Site of Perforation.	Age.	Hours between Perforation and Operation.	Site of Perforation.
46	8½	Lesser curvature of stomach.	20	4½	Duodenum.
24	3½	Duodenum.	33	7½	Duodenum.
47	23½	Duodenum, death	38	3½	Duodenum.
40	25	Duodenum.	24	6	Duodenum.
22	3	Duodenum.	28	2	Posterior surface of stomach.
40	9	Pylorus.	59½	8	Duodenum.

Mortality = 8 per cent.

In conclusion, I do not in any way suggest that the combined operation should be the routine treatment; it depends entirely on opportunity and circumstances. If one is constantly undertaking gastric surgery, and the facilities are favourable, I think the combined operation is both an immediate and remote advantage to the patient, and should be done if the patient's condition will allow it. On the other hand, it should not be undertaken by the "occasional" operator, or in circumstances when warmth, light, skilled assistance, or suitable operative facilities are absent. Simple closure is then the safest method. The complication of bronchopneumonia undoubtedly increased mortality in my earlier cases, but it has latterly almost entirely become eliminated by suitable preparation of the theatre and patient and by careful after-treatment.

TREATMENT OF THREATENED GANGRENE OF THE ARM DUE TO INJURY OF THE MAIN ARTERY.

BY

PETER McEWAN, M.A., M.B., F.R.C.S.ED.,
HONORARY SURGEON, BRADFORD ROYAL INFIRMARY.

In the following two cases, seen several days after the axillary or brachial artery had been torn across, the extent of the threatened gangrene was greatly minimized by a simple method of treatment.

A man, aged 39 years, was admitted to Bradford Royal Infirmary on July 11th, 1925. Five days previously he had been getting off the back of a moving motor lorry, and had been dragged by his left arm for some distance. On admission, the left hand and forearm and the lower third of the upper arm were cold, swollen, and very tense, and did not show any evidence of circulation. The left axilla was occupied by a large, tense, fluctuating swelling, obviously a haematoma, due to rupture of a large vessel, probably the axillary artery. There was no bone injury. It was clear that the collateral circulation had succeeded in reaching only the upper two-thirds of the upper arm, and it appeared possible that the tension under the deep fascia had determined its limit. I accordingly made free incisions through the deep fascia of the arm, down as far as the wrist, so as thoroughly to relieve all tension. During the following ten days warmth gradually returned to the part, extending about one and a half inches further down each day, until it eventually reached the level of the proximal phalanges. Gangrene, however, appeared in the fingers, and presently involved the whole of the hand. Amputation was performed on August 6th at the wrist-joint. He was discharged from hospital on August 20th, and his wounds were all soundly healed by December 6th, his forearm being quite useful and showing no trophic changes. The fluid swelling

in the axilla became gradually and completely organized, with free movement.

On July 19th, 1925, I was asked to see a similar case with a view to giving an opinion as to the site of amputation for impending gangrene.

A child, aged 5 years, had, three and a half days before, sustained a severe fracture-dislocation of the right elbow. This was reduced and put up on a rectangular splint. Two days later the fingers were observed to be blue and cold, and the splint was removed and the arm watched. The condition was not due to tight bandaging. When I saw the child the hand and forearm up to beyond the elbow were quite cold, with some blebs on the skin below the elbow. The forearm up to beyond the elbow was very tense. There was a good deal of ecchymosis over the lower part of the brachial artery, which we presumed was torn. On the analogy of the previous case, I made very free incisions in the deep fascia over the whole area of tension. The flexor sublimis digitorum was found to be already gangrenous. Within twelve hours normal warmth had been restored as far as the wrist, and partial warmth, which soon became complete, in the hand and fingers. Both the flexor sublimis and the flexor profundus sloughed down to the radius, after which the wound healed. Suppuration occurred in the wrist-joint, in which, on October 31st, the date when a note was last made, sinuses still persisted. No amputation was necessary.

It may be deduced that a slight collateral arterial circulation existed after the accident in both cases, but that the tension obstructed the venous return, and thus there was a further increase of tension which inhibited the feeble arterial flow. The tissues bulged freely after the incision of the fascia, and this, together with the rapid improvement in the case of the child, justifies the inference that relief of tension was the essential point in treatment. The absence of interference with the actual lesion of the artery, leaving the collateral circulation as intact as possible, no doubt contributed to the successful result. In the case of the man the recovery of vitality after the limb had been practically or entirely devoid of circulation for days is remarkable.

MEDICAL, SURGICAL, OBSTETRICAL.

NOVASUROL AND OTHER DIURETICS IN CARDIAC OEDEMA.

THE article in the issue of the *JOURNAL* of January 16th (p. 80) by Dr. C. G. Lambie on the diuretic action of novasurol interested me greatly. Following the lines suggested by Keith,¹ Rowntree,² and others I have, so far, treated two cases with striking results, the method employed only differing from that of Dr. Lambie in that ammonium chloride was used, both as a preliminary diuretic and also during the administration of the novasurol itself.

Case I was a woman, aged 67, with myocardial degeneration but no valvular disease. Extra-systoles were present. The lower limbs were enormously oedematous; the dropsical effusion extended to the subcutaneous tissues of the back and abdomen, and also slightly to the hands. A moderate degree of ascites was present, and there was also slight jaundice. Rest in bed over a period of some weeks, Karel diet, the administration of digitalis alternatively with other cardiac tonics, and the use of diuretics such as theobromine sodium salicylate and theocin all failed, the oedema growing steadily worse. Ammonium chloride was then administered in capsules, to a daily total of 5 grams, in divided doses. Low salt fluid diet alone was allowed, and the daily intake restricted to 800 c.cm. By this means a slight diuresis was induced. Novasurol was then given on four occasions at intervals of three days, by the intramuscular route, each dose consisting of 0.5 c.cm. Following each injection the urine increased markedly in amount, with a corresponding decrease in oedema, but unfortunately the attendants could not be prevailed upon to preserve the total for measurement. At the end of thirteen days all oedema had completely disappeared, to the relief of distressing symptoms formerly present. Gradual myocardial failure, however, supervened, and the patient died some days later, without, however, a return of the dropsy.

Case II was that of a man, aged 46, suffering from chronic nephritis with salt retention, albumin being present in the urine to the extent of 4 per cent. The legs were greatly swollen, with severe ascites and oedema of both lung bases. Treatment was adopted on similar lines with fluid intake restriction to 28 oz., and the urine, which before treatment amounted to 25 oz. a day,

¹ Keith, Barrier, and Whelan: The Diuretic Action of Ammonium Chloride and Novasurol in Cases of Nephritis with Oedema, *Journ. Amer. Med. Assoc.*, September 12th, 1925.

² Rowntree, Keith, and Barrier: Novasurol in the Treatment of Ascites with Hepatic Disease, *Ibid.*, October 17th, 1925.

rose immediately under the administration of ammonium chloride to a daily output of 30 oz. Novasurol was given intramuscularly, on the first occasion 0.5 c.cm. and on the second 0.75 c.cm. After the former the output of urine in twenty-four hours rose to 100 oz., and after the latter to 200 oz. The patient was greatly relieved, and only slight oedema of the legs remained.

I was much impressed by these results, and feel that novasurol is destined to prove a very valuable diuretic. It appears to act more rapidly in the relief of ascites than in that of general tissue oedema, and thus may prove more useful still in cases of portal cirrhosis. I have so far found only one toxic disadvantage—namely, the production of a profuse watery diarrhoea for some hours after its administration. This occurred in Case I, and I have since thought it wise to warn patients of this possibility beforehand.

RICHARD HOWARTH, M.B., Ch.B. Edin.

Stalybridge.

A FORTUNATE ESCAPE FROM SYMPATHETIC OPHTHALMIA.

IN July, 1925, a patient presented himself with a piece of chisel firmly embedded in the left cornea; at the end of the wound nearest the pupil there was some escape of aqueous humour and prolapse of the iris. After thorough cleansing with warm boric lotion, the iris was replaced and a fine catgut suture inserted in the cornea; the eye was next treated with 10 per cent. argyrol, covered with a shade, and a plane lens of green glass was fitted over the other eye. He was sent to an ophthalmic surgeon on the third day, who advised immediate excision; the patient refused operation, so was treated on general lines—namely, warm boric fomentations, with atropine "drops." The ophthalmoscopic picture consisted of a grossly injected retinal system, visual acuity was limited to counting fingers at a distance of 1 metre in the injured eye, and 6/9 in the uninjured eye. For twenty-one days he seemed to make little progress, and complained of frontal headache, nausea, and "floating bodies." His fundi were examined every other day, and treatment with boric fomentations, atropine, and 10 per cent. argyrol continued; in addition, his diet was restricted, saline purges given, and oxyquinolothin cachets, which latter relieved his frontal headache.

Not until September 1st did his signs and symptoms show real improvement; on September 10th spectacles were provided to correct his amblyopia, and his vision was 6/12 and 6/9 in the injured and uninjured eyes respectively. He is now working on a stationary engine and carrying out his duties effectively.

I believe that this patient narrowly escaped sympathetic inflammation; it is obvious that he had a marked degree of sympathetic irritation. Although non-excision of the affected eye was not followed by disaster, I am still convinced that in such cases as this the policy of "wait and see" is very apt to develop into "wait and see not."

LAWSON L. STEELE.

TORSION OF FALLOPIAN TUBE.

MR. JOHN C. JEFFERSON's account of a case of torsion of the Fallopian tube (January 9th, p. 55) leads me to report a similar case.

A single woman, aged 23, was admitted to Cheltenham General Hospital on November 5th, 1925, suffering from an acute condition, thought to be most probably appendicitis. The condition started four days before admission with pain in the left iliac fossa going over to the middle line below the umbilicus. There had been vomiting and pain on micturition for three days. Menstruation had been regular, the last a fortnight before admission.

The abdomen was distended below the umbilicus and tender across from the left side to the right. On rectal examination a tender swelling could be felt in the pouch of Douglas. Temperature 100°, pulse 100.

On opening the abdomen abundant free fluid was found in the pelvis. The left tube was swollen and nearly black from strangulation, due to twisting on itself twice round its long axis, the point of torsion being just opposite the ovary, which was normal. The right tube and ovary were normal; the uterus was slightly enlarged. The tube was removed, and the patient made an uninterrupted recovery. There was no evident cause for the torsion.

I am indebted to Mr. Braine-Hartnell for permission to report this case.

Reports of Societies.

MANIPULATIVE TREATMENT IN MEDICINE AND SURGERY.

At a meeting of the Medical Society of London on January 25th, with the President, Sir HOLBURN WARING, in the chair, a discussion was held on manipulative treatment in medicine and surgery.

Mr. W. ROWLEY BRISTOW, in opening, said that this subject should lend itself well to discussion, if only for the reason that every year or two brought forward a heated controversy in the medical or lay press, or both, on the claims of bonesetters. In the lay press the names of distinguished, usually titled, persons were given who were invariably described as being grateful to an unqualified practitioner. The public had been led to believe by the lay press that bonesetting was not included in the armamentarium of the qualified medical man. It was a platitude that adequate treatment necessitated accurate diagnosis, which in its turn depended upon an understanding of the anatomy and pathology of the part affected. Was it true that these unqualified practitioners, whose fundamental grounding was necessarily inadequate, succeeded where the qualified man failed? On the contrary, everyone could recount instances of patients who had failed to benefit at the hands of the bonesetter and had responded readily and well to the recognized medical practitioner. Everyone could also tell of egregious mistakes on the part of the bonesetter. Mr. Bristow related several; one concerned a child, admitted under his care at St. Thomas's, who had been under a bonesetter for some months because she walked badly, and manipulative treatment of the spine had been ineffectual because the child was suffering from congenital dislocation of the hip. The inability to make a correct diagnosis in a simple case was the greatest danger of unqualified practice. He knew of another case of foot-strain in a lady who taught folk-dancing. The bonesetter told her that the ankles, knees, hips, and spine were all "out," and that two weeks' treatment in his home was necessary. Her suspicions were aroused when she discovered that the very same cure had been offered by the same man to her husband, who had suffered from osteoarthritis for many years and was a hopeless cripple. Thus there was reason to believe that the failures of the unqualified were many, but, on the other hand, he did not wish to imply that the qualified man always succeeded and the bonesetter always failed. One man might fail with a patient when another, no better armed and with no greater experience, succeeded. Many men with no very obvious qualifications succeeded well, while the more highly qualified were failures. Personality and experience counted for much, and often gave good results, even when the work was empirical; but if empiricism rather than knowledge was the foundation on which a man worked errors must creep in. The unqualified practitioner sometimes scored because he took risks which the qualified man would not take. The qualified man, if not sure of his diagnosis, had to play for safety. The speaker went on to say that from time to time when manipulative surgery was discussed by members of the profession it was hinted that there was some manipulative art which had been handed down outside the ranks of the regular practitioner, and which he would not, or could not, acquire. The matter was really very simple and had been admirably stated by Sir Robert Jones: "There are no hidden or mystic rites in the art of bonesetting." The methods of manipulative treatment were not absorbed into the general practice of medicine because the teachers in the medical schools had not recognized their value. That was true in the past and to some extent to-day. The field for manipulative surgery was largely in the treatment of minor injuries, and, to a less extent, chronic joint disease. This was the type of condition which lost its perspective in hospital practice, where the graver conditions arrested the attention of the surgeon. There would seem to be no room or time in hospital for adequate attention to those minor disorders, which, however, ceased to be minor as soon as the student

left the hospital and went out into practice. It would be wise for those who controlled medical education to examine whether, in the huge curriculum which now obtained, sufficient time and care was given to the instruction of the student in those minor ailments which bulked so large in practice. Manipulative treatment, its principles and practice, should be brought more prominently before the student. Mr. Bristow passed to consider some of the conditions, resulting from injury or from disease, which were benefited by manipulative treatment, and gave examples. It was difficult, if not impossible, to lay down rules or define the exact indications for the use of manipulative treatment in dealing with chronic joint disease—whether, on the one hand, a stiff shoulder should be treated with rest and warmth, or, on the other, forced manipulation should be advised. The diagnosis must be relied on. If there was active inflammation manipulation would lead to disaster, but manipulation might meet with success if the acute stage was passed and there was limitation of movement. In addition to appreciating the pathological state of the particular joint, an estimate must be formed of the personality of the patient, whether he would be willing to put up with the necessary pain and to follow the treatment through. He urged again that the student should be trained in the use of manipulative methods, and that the advantages and limitations of the treatment should be brought before him.

Mr. R. C. ELMSIE said that manipulative methods as carried out by unqualified practitioners might be roughly divided into two classes: (1) manipulations of the affected part—for example, for adhesions around the shoulder or wrist; and (2) manipulations of some other part not obviously affected—for example, of the spine, as carried out by the osteopath. To take the second group first, in most cases the whole procedure was so obviously irrational that it was difficult to understand how the public were continually taken in by those who practised it. To manipulate a stiff or disabled knee was reasonable, but to manipulate the cervical spine for goitre or diphtheria, the dorsal spine for gastric ulcer, or any part of the spine for epilepsy sounded so ridiculous that it was hardly necessary to subject the methods to criticism. It was perfectly true that passive and active movements of joints might have a considerable effect on certain visceral disorders. The medical side of the work of the masseur had been neglected in the past, and it would repay some young physician to take the matter up and to see whether careful investigation would not disclose a greater use for this type of treatment. With regard to manipulations of the affected part, it must not be forgotten that some bonesetters had a certain knowledge of anatomy and pathology; at any rate, the users of these methods gained experience, and seemed to profit by it in avoiding obvious errors. Sometimes they made very evident misstatements; thus they would say that a small bone was out of place when there was no bone to be out of place at all. It was difficult to say whether these misstatements were the result of ignorance or were deliberately made to impress their patients. Certain bonesetters, if a patient came with a disability of the ankle, informed him that his ankle, knee, and hip were all "out" and must be manipulated, and rule-of-thumb manipulations were made which were sometimes successful, but at other times, particularly in the case of neurotic patients, had quite different results. In one case under his notice a small foot disability was treated by manipulation of the lumbar spine and pelvis. The foot got right, but left a persistent obsession, the patient believing that the whole spine and pelvis had been put out by the manipulator. The obsession had become so severe that she must now be regarded as on the border-line of insanity. Why was it that reports of cases in which the unqualified had done good after the qualified had failed were so frequent? Obviously, cases in which the qualified scored their triumphs were not reported, because reputable members of the medical and surgical profession did not advertise in the lay press. Some years ago he himself treated the stroke of one of the university boats for knee trouble a week before the race. He was back in his boat within twenty-four hours. Had the treatment been carried out by a bonesetter the circumstance would have

had a central place in the newspapers of the day. It was also an undoubted fact that only the successes of the unqualified bonesetter were recorded; his failures remained hidden. The patient felt that he had been "done" and had wasted his money, but he said nothing of the incident to his friends, nor to the surgeon whom he visited later. In some cases there was more than failure—the patient was made worse. It was to be admitted, of course, that surgery of all kinds was not an exact science. Most orthopaedic surgeons had made the mistake of diagnosing a joint suffering from trauma as being tuberculous, or a tuberculous joint as traumatic in origin. Moreover, the responsibility of the surgeon was greater than that of the unqualified man; he was less inclined to take risks, and it was difficult to decide the exact stage at which manipulation was advisable. It was quite untrue to say that manipulative treatments were not used in the medical profession; he personally had used them since he first took up his specialty, and at St. Bartholomew's he followed Paget, Marsh, and Walsham, whose names should be honoured in this branch of medicine. The qualified surgeon was just as capable of carrying out manipulative methods as the unqualified practitioner; indeed, if a strict comparison were made, the surgeon, because of his experience of other methods, was likely to be more successful in this practice. He had come more and more to the conclusion that careful x-ray examination was essential before manipulation. He had had the misfortune to manipulate a tuberculous tarsus which had been declared negative after such an examination; on the other hand, he had cured by manipulation a number of cases of disability of the ankle which had been treated for long periods as being tuberculous. In manipulating a joint for adhesions it was necessary beforehand to determine exactly what movement was restricted and painful. Derangements of joints due to the displacement of an intra-articular meniscus constituted the greatest group of cases in which manipulation was practised. At the present time the surgical exploration of the knee-joint, carried out by a competent operator, was a safe proceeding, and, moreover, promised a certain cure if a definite lesion was found. Therefore, whilst he believed that there were many cases in which one ought to manipulate and might reasonably expect a cure by this method, he maintained that in many operations was essential, and in many others it was the safest method. Almost every case of derangement of the knee on which he had operated had been previously subjected to manipulation. The foot was responsible for many successes of the bonesetters. Owing to the nature and fitting of the shoes, the movements of the foot, and particularly of the toes, were habitually cramped and the muscles went out of action. The bonesetter announced that the toes were dislocated, and by manipulating them restored their mobility and gave comfort to the patient. With due training a good masseur could cure this condition easily in a few treatments. The work of the massage profession, which had previously been stereotyped on Swedish lines, had improved of recent years as the result of close co-operation with surgeons.

Dr. H. A. DRS VORTEX agreed with what had been said about the neglect of this subject in the medical schools. In his own time as a student—and he believed it was the case to-day—men constantly left the hospitals knowing nothing about these conditions and their treatment, only to find on going into general practice how frequent such conditions were. The difficulty of diagnosis in the surprising variety of derangements of the knee-joint made the general practitioner refrain from doing the proper manipulation. There was a medical side of manipulation which he thought very important—namely, that which had to do with referred pains. One often saw cases in which the patients themselves had diagnosed their condition as neuritis, but there was no true sign of neuritis at all, and in these cases in which the pain was often in the arm, less frequently in the leg, on examining the joints carefully stiffness and adhesions would be found somewhere about the shoulder or the hip joint. Careful manipulation of these joints would in a great number of cases cure this type of pain. Very often it would be found that, perhaps as much as a year or two previously, the patient had sustained an injury to the joint.

Mr. T. H. OPENSHAW told of a remarkable case of which he had experience twenty years ago. A girl was brought to the London Hospital for a hip condition, and after three months' treatment the hip, which had previously come out of joint irrespective of her volition, was restored to the extent that it came out of joint only when she wanted it to do so. Some five years later, in a town in the North, he discovered the travelling exhibition of a bonesetter where this girl was paid five shillings a night to exhibit. She walked on to the stage wearing her splints, the bonesetter called a doctor from the audience to certify that the hip was out, then he threw away the walking instruments and pretended to manipulate the hip, the girl herself gave the necessary wrench, and walked down from the stage fully restored.

Mr. ARTHUR EDMUNDS denied that general surgeons in London hospitals took no interest in bones and joints. They were handicapped, however, by the fact that they had only a few beds under their care, and the cases, which did require very careful observation, tended to accumulate in out-patient departments. His old teacher, Sir Watson Cheyne, had been especially keen to teach him that for restricted movements following upon injury the joints should be manipulated. He thought it a great pity that so many of these minor cases did not get admitted to hospital, where they could be thoroughly studied.

Dr. W. W. STROCKER said that during his thirty-four years in general practice he had never tried to prevent his patients from going to bonesetters if they were set upon doing so, and in not a single instance had he seen any success. It was of no use arguing with such patients, they were hypnotized by the newspapers, and in the press itself any statements contradicting the line of its "stunt" were not likely to be published. What was needed was public education and the expenditure of rather more time by qualified practitioners in the study of these conditions and their treatment.

Dr. C. L. TRAYLEN related some cases in which a patient, suffering from more or less severe pain, was able to recall, after being carefully questioned, that some time previously he had had a fall or other mishap, of which he had thought nothing at the time, but which was evidently the origin of the trouble.

Dr. P. B. SPURGIN thought that the reason why the medical profession appeared by comparison to fail in dealing with these conditions was its diffidence in view of the great increase of knowledge which had come about during the last twenty or thirty years. It was a case of fools stepping in where angels feared to tread. In former days there were many cases of quite severe lesions treated by manipulative means, sometimes with success and sometimes not. The practitioner would rather be withheld from treating such cases in that way to-day because he knew so much more about them. It was noteworthy that some of the greatest exponents of mechanical manipulation lived in the era before x rays were available. Dr. Spurgin also remarked that the very complexity of science and abundance of knowledge made one more likely to overlook simple explanations in searching for explanations more remote.

Mr. J. E. H. ROBERTS thought it a pity that this very large subject should be taken out of the hands of the general practitioner and the general surgeon and pass into the hands of bonesetters, osteopaths, chiropractors—and orthopaedic surgeons! (Laughter.) He held that there was far too much specialism in the profession. It was true that orthopaedic surgeons had advanced the knowledge of their branch of surgery in the last twenty years in a way which did not hold good of any other branch, and as long as a surgeon was advancing his specialty he had every justification for existence. But the speaker thought that the knowledge should be more diffused so that in suitable cases the general man could make use of these methods. One type of case to which study should be directed was that in which joints showed a condition resembling tuberculosis, and yet were not tuberculous. Another very common type of case was one in which there was pain in the back, due originally to trauma. He felt sure that the student did not as a rule receive instruction in such cases. These cases should be demonstrated to students in every out-patient department as a definite part of their teaching.

Mr. WHITCHURCH HOWELL said that he had two medical friends who had been treated by bonesetters, one with success and one without. They were both attached to famous medical schools, but neither of them wished to see an orthopaedic surgeon! One had an arthritis of the neck, and no x-ray photograph was taken before the bonesetter manipulated it. The other had sciatica, with a very bad limp, which had gone on for several months. This patient went into a home, and was manipulated several times by the bonesetter. There was now loss of sensation on the outer side of the foot, and it might be necessary to have the little toe amputated. During the last three weeks he had seen a case which was under a bonesetter; it was the case of a child three or four years of age, who was going twice a week to this bonesetter for manipulation for congenital absence of the right radius! (Laughter.)

Mr. DUDLEY BUXTON said that bonesetters, unless they were very inexperienced, seldom manipulated for tuberculous conditions. An early case of tuberculosis did not often go to the bonesetter, and a tuberculous joint in a more advanced state was very obvious, and the bonesetter realized that there was here something which he could not touch. One thing which had struck him in dealing with patients was that so many who went to the bonesetters did not realize that the bonesetters, who announced themselves on a brass plate, were not qualified medical men. While it was true that there was a good deal of conservatism among the senior men in the medical profession with regard to manipulation, he thought that the younger surgeons were out for this method in cases in which the indications were definite, but they hesitated at cases on the border-line.

Dr. A. C. JORDAN suggested—a suggestion which Mr. Elmslie said in his subsequent reply "appalled" him—that the proper thing to do would be to create a band of osteopaths who, unlike the present osteopaths, would act under doctors' orders, in the same way as masseurs.

The PRESIDENT (Sir Holburt Waring) took up the statement with regard to medical schools. He quite agreed that something more might be done in the way of teaching in manipulative surgery. Not very long ago, when the revision of the medical curriculum was considered by the General Medical Council, a committee of the Council discussed this question in considerable detail. A recommendation was issued to the licensing bodies, and through them to the schools, that "mechano-therapeutics" should be an essential point in the curriculum. By the term "mechano-therapeutics" it was intended to convey what had been referred to as manipulative surgery. The difficulty in the hospitals was that the number of beds which each surgeon had at his command was necessarily limited, and were utilized for the more serious cases. A large number of patients who came to the out-patient department with various conditions which might be best treated by some form of manipulative surgery were, in the main, treated by the house-surgeon, and never got as far as the assistant surgeon or the surgeon. He could not agree with Dr. Des Voeux that surgeons in general forgot these cases, but they had so much to do in other ways that it was not always possible for them to impress on the rising generation the importance of these relatively minor things. On a more general question his experience was that general practitioners were rather afraid of bold treatment in such conditions. In the later period of the war a good deal of his time was occupied in doing manipulative surgery, and he found it very general among officers of the R.A.M.C. to be rather afraid of this class of treatment, and he believed it was the same in general practice. Something had been said about the newspaper press. The press dearly loved to start a "stunt" against some statutory body, and it was a very easy matter for the irregular practitioner to get very favourable notices in a considerable portion of the press, whereas communications containing facts which cut across the "stunt" were ignored. This whole matter might be expected to come forward very prominently during the present year.

Mr. BRISTOW, in a brief reply, demurred to the name "mechano-therapeutics" as descriptive of manipulative surgery. To him the name signified those departments in military hospitals in which there were masses of apparatus

for body exercises. It was not a very impressive term to use in advising school councils.

Mr. ELMSLIE agreed with one speaker that many members of the public appeared to think that where manipulation was required the right person to go to was a bonesetter or osteopath, not a medical man; many did not realize that the medical man carried out, or professed to carry out, manipulative treatment. This, again, was due to the attitude of the press. He mentioned that, following upon Mr. Bernard Shaw's recent criticism of the training of masseurs and masseuses, the medical members of the council of the Chartered Society of Massage and Medical Gymnastics had addressed to the influential journal in which the criticism appeared a correction to the effect that the training of the masseur in England was not a few weeks, as Mr. Shaw had stated, but a minimum of twelve months, and for practical purposes eighteen months. The letter had not been inserted!

HYPERPIESIS.

DEBATE AT THE ROYAL SOCIETY OF MEDICINE.

At a general meeting on January 25th, the President of the Society, Sir STCLAIR THOMSON, in the chair, LORD DAWSON OF PENN opened a discussion on hyperpiesis.

Lord Dawson, after referring to Sir Clifford Allbutt, said that he preferred the term "hyperpiesis" to "hypertension" because the key to the disease and the hope of alleviating it lay in a study of its beginnings. Supertension had no rigid limits or defined boundaries, and passed gradually, perhaps silently, into states of disease, as manifested, for example, by damaged arteries or defeated hearts. But these latter he did not propose to discuss, nor would he deal directly with prognosis and treatment. An essential question was whether supertension was necessarily associated with change of structure. In its beginnings was it a disturbance of function which led to changes of structure, or was it preceded and produced by change of structure? One way of answering the question was to conduct an inquiry among younger and apparently healthy people, thus avoiding the perplexing association of arterio-sclerosis. One group of people had an over-responsive vasomotor system, just as others suffered from nervous dyspepsia or diarrhoea. These very responsive people were liable to develop transient supertension when exposed to physical or psychological stress. Commonly their blood pressure at rest was above normal, but not always. It might even be a family trait. Usually the activating cause was apprehension, and anxiety for success, the link between the higher centres and the vasomotor centre being too intimate. For illustration Lord Dawson described the cases of three boys of school age, apparently of a similar state of health and demeanour. Two of them had a normal blood pressure. In the case of boy "A," the rest pressure was 125/60, pulse 78; after he had run rapidly up seventy-two stairs the pressures were 162/65, and the pulse 114. After lying down for six minutes the pressures had dropped to 120/60, and the pulse was 100. In the case of "B," at rest the figures were 110/65, pulse 85. After running up seventy-two stairs these figures became 135/70, the pulse being 104. After three minutes of recumbency the numbers were 120/70, and the pulse 90. In contrast he gave the case of "C." This boy's pressures were 135/70. After running up the same stairs they were 170/85, and the pulse 144. After even twenty minutes of recumbency these did not fall below 130/70, and the pulse was 90. He had an over-sensitive vasomotor system, but the speaker believed that the sensitiveness was transient. Yet the potentialities of hyperpiesia were present. What was in store for the boy would depend upon circumstances; whether his temperament was placid, or eager and over-anxious; and on the nature of his employment. His tension might remain within the normal until the responsibilities of maturity and the metabolic imperfections of middle life reinforced his tendency. Lord Dawson then referred to the examination of 580 undergraduates of Toronto, whose average pressure was 126.5/71; 10 per cent. of them had a systolic pressure of over 140. In another group of 15,000

undergraduates Alvarez found that over 20 per cent. had more than 140 systolic pressure. Of 650 healthy school children between 10 and 17, investigated by Lord Dawson and his colleagues, 52 had supertension, and in a few of these cases there was a long-lasting and well defined thickening of the arteries and an enlarged heart. There was, he said, evidence that high blood pressure—transient, intermittent, or even permanent—existed among the young. With many it was a passing phase, but some of the cases of intermittent hyperpiesis seemed to produce cardiac enlargement, accentuation of the second aortic sound, and left-sided preponderance. Were they, he asked, a reaction to modern civilization in the form of a raised excitability of the vasomotor centre? Strickland Goodall, in America, had examined 2,000 cases under the age of 40, and found the most frequent antecedent was scarlet fever. This was in favour of the infective origin of hyperpiesis and supported the contention that hyperplastic sclerosis of the intima was the underlying change found in hyperpiesia. But scarlet fever was not a factor in all cases, and Lord Dawson asked whether there was not to-day too great a bias in favour of infections as the cause of illness. Was enough weight given to the character of the soil—the internal factor? It was difficult to believe these healthy young people were victims of an infection. With regard to overresponsiveness of the vasomotor centre in adults, he made use, as illustrations, of two of Frost's cases, who were subjects of mental stress and anxiety. The first patient, aged 36, had a rest pressure of 148, which under effort tests rose to 220. Later, when there was no mental stress, similar tests raised the pressure to 144 from 118. In this case there was too great a vaso-constrictor responsiveness. The second patient, a man aged 41, had a rest pressure of 150/100, which under effort tests went up to 246. At this man had moderate hypertrophy of the heart structural change had actually begun. With these Lord Dawson contrasted the case of a worrying anxious woman, aged 35, whose vasomotor centre did not show this selective responsiveness, but who, conversely, could be said to "feel abdominally." Her rest pressure was 110/80, and under fatigue it easily fell to 100. After quick exercise it became 155/80, returning, after two minutes' lying down, to 110/90. The next stage in the development, he suggested, was that the rest pressure reached a higher level; then the patient usually complained of headache, throbbing, and other symptoms. The diastolic pressure was of the greater importance, because that indicated the enduring strain on the arteries. If the diastolic pressure was not above 100 and there was no advanced arterio-sclerosis a systolic pressure prone to rise easily need not cause alarm. In youth he liked to see a diastolic pressure at about 70 to 80.

Lord Dawson referred in some detail to a case which illustrated a fixed supertension in youth, that of a girl aged 23, who looked and felt well and entered into work and play. But she became tired with a full day's work, and after heavy exercise was breathless; she was therefore placed on half-time work. Early in childhood she had had scarlet fever; she still had occasional headaches, but fewer than formerly. Her pressure was 250/150, and had so remained for a number of years. After running up and down seventy-five easy stairs the blood pressure was 280/150, returning to 240/140 after ten minutes' recumbency. After a month in bed, with careful dieting and drug treatment, her rest pressure fell to 165, but a few minutes' walk on the level raised it to 215. Both her parents had a blood pressure on the high side, and her younger sister had a rest pressure of 160/100. The patient's blood urea and kidney function tests were within normal. Her radial arteries were too palpable, but not hard; the heart was enlarged and there was an accentuated aortic second sound preceded sometimes by a systolic bruit. Three noteworthy changes were found in the kidneys: thickening of the media of the medium-sized arteries, slight thickening of the intima of the smaller vessels, and patches of atrophic tubules. The thickening of the muscular coat, he considered, followed the continued vaso-constriction. In sections which were shown, small vessels could be made

out with the intima swollen and structureless; thus changes due to hyperplastic sclerosis were present, though these were far less permanent than the medial changes. These signs seemed to indicate a selectivity for the vessels of the kidney, pancreas, and spleen. Fashberg, in seventy-two necropsies on patients who died of hypertension, found that in all the minute arterioles of the kidney were affected, in 66 per cent. the splenic arterioles were involved, and in 50 per cent. the pancreatic. In middle and later life, when arterial degeneration was apt to occur, hyperplastic sclerosis might closely follow hyperpiesis, or might even coincide with it. Lord Dawson said he had emphasized hyperpiesis in youth with the object of showing that, in its inception, it was a functional disease, and because at this age the problem could be kept clearer of the complication of athero-sclerosis. The association of hyperpiesis with the climacteric, with eclampsia, and with the "blubber" type of obesity, indicated that there was some warp of metabolism. Experimental evidence suggested that too much importance had been attached to the protein and salt intake, but some authorities considered that more than a minimal consumption of protein was harmful. The subsequent anatomical changes which led, by steady progression, to the developed disease, were probably one and the same, whatever the origin might be.

Professor F. R. FRASER first reviewed briefly the physiological and pathological knowledge which was available as a basis for the proper understanding of the condition. The mean arterial pressure depended on the output of the heart and on the peripheral resistance; Lord Dawson's observations on children pointed to the changes in the heart as being secondary, and he would therefore deal only with factors influencing the peripheral resistance. In health this was so regulated by reflex mechanisms that an adequate amount of blood was supplied to all tissues. Of principal importance was the vasomotor centre in the medulla. Brief variations in the mean pressure were continually occurring as the result of reaction to environment, and there were certain facts known with regard to these adjustments. An inadequate supply of blood to the vasomotor centre caused a rise of general arterial pressure; the vasomotor centre was also stimulated by peripheral stimuli, such as those of pain; general arteriole constriction could also be produced by the higher portions of the cerebrum, such as occurred in emotional states. How far this might be due to the internal secretion of the adrenal bodies was uncertain, but the conclusion must be that chemical substances, such as internal secretions in the circulation, could produce a rise in the general arterial pressure. Further, it was obvious that structural changes in the smaller vessels constricting their lumen would, if sufficiently widespread, raise the general pressure, and that the same result would be produced by changes in the blood increasing the resistance to flow, as in erythrocythaemia. Dealing with the various factors in turn, Professor Fraser said it was unlikely that inadequate blood supply to the vasomotor centre could be the cause in many cases without the reason for the inadequacy having been discovered in some; he knew of no evidence in favour of this mechanism. It was difficult to understand how reflex stimulation of the centre from the periphery, or by the emotional or anticipatory states, could result in a persistent rise of pressure; clinical observation, however, and the result of certain therapeutic measures did seem to favour such a causal relation. Possibly by some adaptation, such as was involved in the establishment of "conditional reflexes," the frequently repeated exposure to physical and mental stresses might result in a persistent vasomotor stimulation. Cases in which the condition arose at adolescence or about the menopause were suggestive of an origin dependent on disturbances of internal secretion. It was also probable that some cases were due to pre-existing, but unrecognizable, renal or vascular disease. Professor Fraser pleaded for a thorough investigation in every early case of all factors, constitutional, environmental, dietary, etc., for a more extended use of the sphygmomanometer, and particularly for a record of the diastolic pressure, which he considered a much better guide to peripheral resistance than the systolic.

Dr. PARKES WEBER said he thought Jews were more liable than other people to have permanently high blood pressure. He did not agree with Professor Fraser that high blood pressure was produced by an excess of erythrocytes in the blood. He did not think the increased wear and tear of life could be accepted as a cause of hyperpiesia in normal individuals. Starling had well shown that the normal needs of the brain would maintain blood pressure if there was a danger that the supply of blood might be deficient. The increased blood pressure at or about middle life showed that the cerebral circulation was becoming relatively defective, owing to changes in the capillaries there. A great mistake made by the people under discussion was to take more food at middle life, as this added to their troubles.

Dr. J. A. RYLE pointed out that careful reading of the old writings of Bright, Gull and Sutton, and Mahomed showed that the views held on hyperpiesis to-day had been clearly in their minds nearly fifty years ago. He had recently classified the cases of hyperpiesis according to physique, and he found that 62 per cent. fell into the hypersthenic group. In this group he thought it was vain to look for signs of infection or toxæmia; they were typically healthy people, and the condition was due to overstimulation of their physiological characteristics. About 16 per cent. fell into the group of "poor physique"; these began their diseases earlier, and in them infection and early illnesses might well play some part.

Dr. DOROTHY HARE mentioned the variations which occurred, and must be allowed for, in the blood pressure readings of the same individual under uniform conditions, at short intervals of time, her table showing as much as 10 to 20 mm. variation in this way. To reduce the variations she suggested that a rule should be made to examine the right arm in each case.

Sir JOHN BROADBENT thought it could be taken as certain that some families were born with a tendency to high blood pressure, others with a tendency for it to be low. There could not be high blood pressure without some cause of peripheral resistance also existing. Arterial hypertension was a characteristic of the kind of cases under discussion. In simple hyperpiesis he did not think the kidneys could be incriminated, but the profession was still without knowledge as to the toxin responsible for the condition.

Dr. HENRY ELLIS said one type of this condition had always an excess of phosphoric acid in the urine, and the other had a deficiency. Advance would only be made by investigating the free acid as against ammonio-combined acid.

Dr. J. C. BRAMWELL (Manchester) agreed as to the importance of the diastolic pressure in these cases, since the rise in that meant a rise in the mean pressure, and the arterial walls were rendered less extensible. If the diastolic pressure was 120 or 130, the systolic must be round about 240 to maintain anything like an equivalent cardiac output. A rise of diastolic pressure placed a great additional strain on the heart, and increased the liability to cerebral hæmorrhage, as well as limiting the body's oxygen intake.

Dr. HALLS DALLY dealt with the questions of classification and nomenclature, and made a plea for uniformity in the latter.

Dr. C. O. HAWTHORNE suggested that the term "blood pressure" should be abolished, "sphygmomanometer reading" being substituted. He agreed that there had not been much advance in the pathology of the condition under discussion.

Dr. BARTON thought the chief value of the opening contribution was the way in which it directed attention to conditions in which blood pressure was high in youth. He gave some results of his own experience. In a general way, he thought knowledge on the subject still stood where it did fifty years ago.

LORD DAWSON, replying, thought attempts at alterations in terminology should be gradual and in the nature of a compromise. In answer to points raised in the discussion, he elaborated in more detail some of the arguments submitted in his paper.

ADDRESS BY DR. J. A. RYLE.

At a meeting of the Buxton Medical Research Society on January 12th Dr. J. A. RYLE delivered an address on hyperpiesia and hyperpiesis.

Dr. Ryle first reviewed the work of the earlier pioneers, including Bright, Gull and Sutton, and Mahomed, and paid tribute to the great services rendered by the late Sir Clifford Allbutt in delimiting hyperpiesia from renal and other forms of hyperpiesis on the one hand, and from senile or decreascent atheroma on the other; he then proceeded to discuss the present state of knowledge regarding the etiology and pathology of the disease. He suggested that, although it was interesting to speculate about the existence and nature of a pressor substance, it was at present more profitable to bear in mind certain known etiological factors, and uttered a warning against the neglect of earlier methods of clinical study in the endeavour to unearth the specific causal agents. He regarded bacterial and intestinal toxins as unlikely factors, partly because most of these toxins had a depressor rather than a pressor effect, and partly because the majority of hyperpietic patients had been robust and healthy individuals with a striking immunity from infection. The question of diathesis was of particular importance in hyperpiesia. It had long been recognized that hyperpiesia was more common in robust individuals, and that there was frequently a family history of deaths from cerebral haemorrhage or "cardiac defeat" in the fifth and sixth decades. An analysis of fifty cases of hyperpiesia which he had made resulted as follows: 62 per cent. of the patients were recorded as "robust," "healthy," "stout," "plethoric," or "hypersthenic"; 18 per cent. as "average"; 14 per cent. as "poor physique"; 6 per cent. as "lean and nervous." The outstanding characters of the hypersthenic diathesis were a full habit, a broad chest, a good colour, and a pronounced tonic of both skeletal and plain muscle. The stomach was hypertonic, and the appetite and capacity for work were exaggerated. He defined "diathesis" as an inherent liability to retain the impress of certain adverse stimuli. Patients with a physiological hypertonus of vascular plain muscle were more likely to retain permanently the effects of stimuli such as overwork, overeating, and over-anxiety, which were normally known to raise the blood pressure. Infections only appeared to play an important part in the small group described under the heading "poor physique" and in a few of the "average" group. The high incidence of the female cases—54 per cent. as compared with 46 per cent. of males in his series—was probably due to the inclusion of cases of menopausal hyperpiesia. Dr. Ryle next reviewed the early and later subjective symptoms and signs of the disease. The incidence of seventeen common symptoms in his series was discussed and the value of routine employment of the sphygmomanometer and ophthalmoscope emphasized. Particular attention was drawn to the question of differential diagnosis from chronic interstitial nephritis; from primary cardiac disease; from neurasthenia; from anxiety states; and (in a small number of cases with haemoptysis and fatigue symptoms) from pulmonary tuberculosis. Prognosis was shown to depend rather upon the response manifested by the heart and arteries to the hyperpiesis than upon the degree of hyperpiesis. The modes of death were enumerated. Finally, among therapeutic measures, the influence of altered mode of life, holidays, dietary, weight reduction, venesection, and diathermy were considered. A special plan was made for prophylaxis based on the popularization of periodic physical examinations after the fourth decade, attention to the family history and physical type, and the systematic use of the sphygmomanometer.

HYDATIDIFORM MOLE.

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, held on January 7th, the President, Mr. T. G. STEVENS, read a communication on a case of hydatidiform mole, with expulsion, and death from pulmonary haemorrhage.

The patient, aged 32, was admitted to hospital on July 17th, 1924, complaining of intermittent haemorrhage for three months; the

last normal period occurred in March. The uterus was too large for a normal pregnancy of four months, and the diagnosis of a hydatidiform mole was made tentatively. On July 18th the cervix was dilated and the diagnosis was confirmed; a small Horrocks's bag was then introduced. On July 22nd, the mole not having been expelled, pituitary extract was given in three-minim doses every two hours. Uterine contractions occurred, and at 9.45 p.m. the mole was expelled. About half a pint of blood was lost during expulsion, and the patient's condition became very bad, the pulse rising to 180 and becoming very feeble. Intravenous gum-saline solution was given, and at 11 there was considerable improvement. At 11.45 the patient coughed up bright red frothy blood and died immediately from asphyxia. At necropsy the lungs showed general oedema, and general ecchymosis of the smaller bronchi. The cause of death was obscure. Sections made from different parts of the placenta, showed that it was the result of the capillaries in the alveolar walls by fragments of deported villi. These seemed to be universally distributed, as sections from several parts showed the same lesions.

Deportation of villi had long been known, but this was the first occasion on which Mr. Stevens had observed any serious results from it, apart from the secondary deposits of chorion-epithelioma. Although the uterus in this case showed some invasion of its walls by trophoblastic proliferations, nothing was found which suggested a chorion-epithelioma. It must be concluded that, normally, deported villi are dead structures and disappear by liquefaction or absorption. In this case they evidently retained their vitality, and exercised their normal function of attacking and opening up blood capillaries, with disastrous results to the patient.

The President also read notes of a case of hydatidiform mole removed by hysterotomy.

The patient, aged 30, had missed one period and then complained of intermittent haemorrhage, with a little pain for several weeks. The uterus reached the umbilicus and was larger than it should have been, assuming that pregnancy had occurred. It was hard in parts, doughy in others. No fluctuation, fluid thrill, or foetal parts were felt. A provisional diagnosis was made of hydatidiform mole, which was confirmed by dilating the cervix and removing a fragment with forceps. A small Horrocks's bag was introduced, but the cervix was very hard and unyielding, and in spite of leaving the bag in four days, putting weights upon it, and giving small doses of pituitary extract intramuscularly, nothing happened. As the patient was very nervous, the cervix very unyielding, and a slight rise of temperature had occurred, it was determined to open the abdomen and remove the mole by incising the uterus. This was done, and proved a very simple procedure, the mole being completely and cleanly removed by turning the uterus partly inside out. The uterine incision was sutured as in a Caesarean section. The patient made an uninterrupted recovery. The succeeding periods were somewhat irregular and abnormal, but six months afterwards the patient was quite well.

Mr. Stevens deduced from this case that when the uterus was sluggish and did not respond to stimulation hysterotomy was the operation of election for hydatidiform mole.

Mr. ARTHUR CROOK had had about eight cases of cystic mole, all of which had been spontaneously expelled. He had made it his practice to explore the cavity of the uterus under a general anaesthetic, going to the fundus if possible with the finger only, to remove any debris that might be there. Also, after the exploration, at an interval of at most a month, he performed curettage, irrespective of the presence or absence of symptoms.

Dr. LOUISA MARTINDALE referred to two cases of hydatidiform mole she had had. In both cases, severe haemorrhage was the symptom calling for immediate intervention. She had had no difficulty in dilating with Hegar's dilators, removing the mole with two fingers and a blunt Rhein-städter's curette. In both cases she had watched the patients for two years after, and there had been no development of chorion-epithelioma.

Carneous Mole.

The PRESIDENT also read particulars of a case of carneous mole retained fifteen months *in utero*.

A woman, aged 23, who had given birth to a child in 1922, had a natural period on August 16th, 1923. A sharp attack of pain occurred on December 22nd, but there was no haemorrhage. At the end of January, 1924, pregnancy of four months' duration was diagnosed. On February 28th the pregnancy appeared normal, and the uterus reached the umbilicus. Soon after this a slight attack of pain and haemorrhage occurred. On April 9th the uterus was smaller, and its upper level reached half-way between the pubis and the umbilicus; no movements were felt. A mole

was diagnosed, and ergot in full doses was given, but apart from a small amount of pain nothing happened. On May 31st the uterus was a little smaller, and the patient felt perfectly well. She was advised to come to hospital for an examination, but did not do so until August 13th, one year after the last natural period. Except for the slight haemorrhage in February, there had been absolute amenorrhoea during the whole of this time. The uterus was enlarged and reached half-way between the umbilicus and pubis; it was very hard, and the upper part appeared spherical, as if it contained a fibroid. The cervix was long, hard, and rigid. She felt perfectly well, and did not wish to have anything done. In October the uterus was found to be unchanged; there had been no haemorrhage in the meantime. Finally, she was admitted to St. Mary's Hospital on November 11th in exactly the same condition. The uterus was so hard and its fundus so spherical in shape that it was thought that there must be a fibroid present, in spite of the amenorrhoea. The possibility of a retained carneous mole was not lost sight of, but the absence of haemorrhage and the shape and consistence of the uterus seemed to negative it. Accordingly an exploratory operation was performed by Mr. Stevens. A vertical incision was made in the anterior surface of the uterus, and it was then seen that the enlargement was due to a retained carneous mole. This had no attachments to the uterine wall, and was removed entire, the uterus being sutured as in a Caesarean section. The patient made an uninterrupted recovery. The mole was a very large one and was solid; the amniotic cavity, being squeezed quite flat, was very difficult to recognize. On section it showed chorionic villi, decidua, and blood clot. The villi showed some degenerative changes, chiefly in the form of accumulation of fluid in the connective tissue core.

There seemed to be no doubt that this was a true case of retention of a mole for fifteen months, as the case was watched the whole time, and at no period was anything passed except a trifling amount of blood on two occasions.

Dr. W. H. F. OXLEY gave particulars of a case of carneous mole, with a history of six months' amenorrhoea. The patient on examination was found to have a uterus about the size of a three months' pregnancy. Carneous mole was diagnosed, but the patient was told to return for a further examination in a month's time. She did not do so, but six months later she passed the carneous mole completely, and made a good recovery.

Dr. J. S. FAIRBairn reported the case of a young married woman with a history of amenorrhoea of about fifteen months, and a hard enlarged uterus that closely simulated one containing a fibroid. The age of the patient and the total absence of menstruation shortly after marriage in one who had been previously regular did not, however, suggest fibromyoma in this case. Three months' trial of various preparations of ergot proving ineffective in exciting uterine action, the cervix was dilated, and a hard mass of old blood clot removed in pieces with some trouble, but almost without any fresh bleeding. He agreed with the President that in treating a vesicular mole an attempt should be made to encourage the uterus to empty itself rather than to remove the mole digitally or otherwise. Cases, however, occurred in which artificial removal was required because of delayed or incomplete expulsion with haemorrhage. He had not found the difficulty as great as the President made out, either in dilating the cervix or in reaching the contained material. He would agree that in all, or nearly all, the cases in question the mole had probably been partially expelled, but by clearing out the lower portions within reach by the finger and those higher up with ovum forceps, and by squeezing down the uterus from the abdomen, he had found it possible ultimately to explore the whole cavity with the finger. The cases were watched carefully afterwards, and in one in which bleeding recurred the uterus was explored again, and an attempt made to remove attached fragments with the curette. The material contained masses of blood fibrin, fragments of muscular wall of the uterus, and degenerate villi without any evidence of cellular proliferation. Nothing further was done, and the patient remained well. He thought the President was treading on dangerous ground in advocating hysterotomy.

Krukenberg Tumours of the Ovary.

Dr. WILFRED SHAW, in a paper on Krukenberg tumours of the ovary, said that the tumours originally described by Krukenberg in 1896 were solid, with smooth surfaces, retaining the shape of the normal ovary, bilateral, and usually accompanied by ascites. Microscopically they had the form of a fibrosarcoma, but, in addition, large signet-ring-like cells were present. Krukenberg considered that these cells were derived from connective tissue cells, and

called the tumour a fibrosarcoma mucocellulare carcinoma-todes, in view of the mucin content of the signet-ring cells and of the attempt at alveolar arrangement that was sometimes seen. It was afterwards shown—particularly by Kraus—that such tumours were usually found in association with carcinoma of the stomach, and at the present time the Krukenberg view of their origin was strongly disputed. Dr. Shaw described five cases of Krukenberg tumour, in four of which there was good evidence that the tumours were secondary to carcinoma of the stomach. In almost all the recorded cases of Krukenberg tumour that had been examined completely at autopsy or at operation a carcinoma of the stomach had been found. It was difficult in many cases to demonstrate that the tumours were secondary in nature unless an autopsy was performed, for the primary growth might be small and missed at operation, while the ovarian tumours were the dominant feature of the case. On the other hand, apparently true Krukenberg tumours had been found in cases where no primary growth had been found at autopsy. It was difficult to agree that the signet-ring cells were derived from connective tissue in view of their mucin content and because of the alveolar arrangement sometimes seen; it was much more likely that they were epithelial structures. In the complete cases recorded the primary growth had been almost invariably carcinoma of the stomach. Ovarian metastases of carcinoma of the sigmoid or caecum frequently resembled Krukenberg tumours, but it was doubtful if a true Krukenberg tumour had been found in association with any growth other than carcinoma of the stomach. The common metastasis of carcinoma of the stomach found in the ovaries was a nodular tumour resembling the primary growth, and these metastases were probably produced by implantation. In the case of Krukenberg tumours this mode of spread did not hold, for cases had been recorded where the peritoneum had been free of growth, and it was difficult to explain the smooth surface and the histological structure of these tumours by this hypothesis. It had therefore been suggested that they were produced by retrograde lymphatic spread—as had been shown to occur in cases of carcinoma of the breast. On this hypothesis it was assumed that the superior lumbar glands were blocked by carcinoma from the primary growth of the stomach, and that the ovarian lymphatics which passed to these glands were invaded by retrograde lymphatic spread. In this way the ovaries were invaded from the medulla and not from the surface, which accounted for the shape of the tumour and for its smooth surface. This hypothesis explained the isolation of the signet-ring cells amongst the stroma cells, and the loss of the characters of the primary growth, for it must be assumed that only isolated cancer cells disseminated along the lymphatics in this way. There was a certain amount of evidence in support of this view. It had been pointed out by Schottlaender that in early metastatic carcinoma of the ovary nodules of growth were frequently found in the medulla when the cortex was free of growth. O. Frankl had shown that in cases of metastatic carcinoma of the ovaries it was possible to demonstrate metastases in the wall of the uterus, while in the cases of primary carcinoma of the ovaries such metastases were not found. Krukenberg emphasized in his paper that the tumours occurred in young women. This was illustrated by the records of cases since recorded. Of 35 cases 9 were found in women between the ages of 21 and 30, 17 between 31 and 40, and only 7—that is, 20 per cent.—in women over the age of 40. This was a very important feature of these tumours, for carcinoma of the stomach occurred most typically in patients over the age of 40. Metastases of carcinoma were found very frequently in the ovaries compared with other organs of the body, and this was well marked in cases of carcinoma of the breast. It had been suggested that the ovaries afforded an excellent culture medium for these metastases, and that the sarcomatous changes in the stroma represented the action of the ovaries to the invasion of the cancer cells. A diagnosis of malignant disease of the ovaries was usually made, for ascites accompanied these tumours, but the immediate mortality of ovariectomy was high, and with modern methods of x-ray examination of the stomach the operation of ovariectomy should be performed less frequently than had been the case in the past.

The PRESIDENT considered that these tumours were more common than was generally thought. Not infrequently they were removed and looked upon as fibromata of the ovary unless a microscopic examination was made. Their histological structure was that of the "leather-bottle" stomach—namely, a carcinoma composed of an embryonic stroma enclosing small alveoli of large epithelial cells, usually arranged in a single row of not more than three or four elements. The epithelial cells always showed a large vacuole, which pushed the nucleus on one side and produced the well known signet-ring appearance. The embryonic stroma, which had often been wrongly looked upon as sarcomatous, was only the response of the ovarian stroma to an unusual stimulus supplied by the secondary epithelial growth. This stroma closely resembled that of many ovarian fibromata, in which the whole growth was often intensely cellular and yet not malignant in any sense. Mr. Stevens had always regarded these tumours as the result of epithelial implantation, but in the light of modern opinion, as shown by Dr. Shaw, he considered that invasion via the lymphatic channels seemed highly improbable. Secondary ovarian carcinomata might follow a primary growth in the stomach, intestine, or breast, but in view of the histological characters of the Krukenberg tumour Mr. Stevens considered that the primary growth was always gastric, as a tumour of intestine or breast never had the peculiar characters usually found in these tumours. The most striking clinical feature was that the cases so seldom showed any gastric symptoms, but only came under observation when the abdomen commenced to enlarge from ascites due to the secondary growths.

ISOLATION OF SPORES AND BACTERIA.

At the meeting of the Pathological Section of the Royal Society of Medicine held on January 19th, Dr. SYDNEY DICKINSON, of the Rothamsted Experimental Station, described a simple method of isolating and handling particular spores and bacteria. The method described consists in holding the bacteria in a film of water and then moving one of them to another part of that film by means of a local thickening, the whole process being observed through an oil immersion lens. In practice the film of water used is that on the surface of a layer of agar on a coverslip, while the local thickening is obtained by bringing a fine glass rod in contact with the agar, and then withdrawing it slightly, so forming a column of water; it is in the column so formed that a bacterium is carried to another part of the agar, and that part is cut off and put into the new culture tube. The glass rod is capable of fine adjustment in all directions, being mounted on a three-movement machine, clamped to the microscope stage, which is called an isolator, being made for the purpose by Messrs. Ogilvy and Co. Dr. Dickinson added that with this machine it was possible, starting from a culture, to isolate a single bacterium and transfer it to a fresh test tube in from three to five minutes.

TESTS OF FUNCTION.

A MEETING of the Leeds and West Riding Medico-Chirurgical Society was held at the Leeds General Infirmary on January 15th, with Mr. A. L. WHITEHEAD in the chair.

Dr. W. MACADAM (Leeds) read a paper entitled "The uses and limitations of function tests in medical and surgical practice." In this he laid stress on the axiom that the simpler the method the more likely was it to prove helpful, and that the lengthy, elaborate, and complex procedures were out of place in clinical medicine. The various function tests were of little value if considered alone; they must always be viewed in relation to the clinical condition of the patient. Nor must inadequate function and disease of an organ be regarded as necessarily synonymous. A study of the amount of urea retention in the blood in conjunction with a comparison of the percentage of urea excreted in the urine was the simplest and safest guide to the state of renal function. But a high

blood urea was found in many conditions other than kidney disease; even a high blood urea plus albuminuria was not sufficient for diagnosis. Examples were given of the applications of these tests in various medical and surgical conditions. So far tests of hepatic function had not yielded the reliable results that renal tests had, and from the medical point of view were disappointing. The most useful was the laevulose test, while the value of such dye tests as phenoltetrachlorophthalein was still uncertain. Van den Bergh's test, although failing to be of much practical value in the clinical differentiation of the various types of jaundice, was proving useful in detecting early or latent jaundice, and in distinguishing between haemolytic and secondary anaemias, etc. The numerous factors that might vitiate estimations of basal metabolism were emphasized, while the failure of the basal metabolic rate as a diagnostic adjunct in those doubtful early cases of hyperthyroidism in which the clinician also was uncertain was discussed. But as a measure of the efficacy of various lines of treatment, and as a guide to the best time for operative procedures in connexion with the thyroid, the basal metabolism rate was of distinct value. The most useful pancreatic tests and their clinical applications were also briefly discussed.

Cases.

Mr. P. J. MOIR (Leeds) showed two cases of hydro-nephrosis. The first was a long-standing case, and the pyelogram taken after the injection of sodium bromide solution into the pelvis of the kidney through a ureteric catheter showed a very large pelvic cavity. In the second case the pyelogram demonstrated an early condition. Mr. Moir emphasized the usefulness of this method of diagnosis and examination.

Dr. WALKER demonstrated for Dr. WARDROP GRIFFITH a case of thoracic aneurysm occurring in a man of 33 years. When admitted to the ward there was a well marked pulsating swelling of the chest, which had subsided with rest and iodides. Dr. Walker expressed the opinion that the condition on admission left room for no doubt that the condition was one of aneurysm; there was no history of syphilis and the Wassermann test was negative. Dr. CURTIS BAIRN (Harrogate) and Dr. VALE (Leeds) both indicated that they were not convinced that this was a case of aneurysm; in their opinion dilatation of the aorta associated with aortic disease, probably rheumatic, was a likely alternative.

Dr. VIXING, in association with Mr. DOBSON (Leeds), showed a child of 4 years upon whom the operation of thoracoplasty had recently been performed for unilateral fibrosis and bronchiectasis following empyema at the age of 11 months. Parts of the sixth to the eleventh ribs had been removed, and Mr. Dobson expressed his opinion that it would be necessary to remove probably two or three more before efficient collapse of the base of the lung was attained. Following the operation there had been an immediate decrease in the quantity of the sputum.

Dr. VIXING (Leeds) also showed a boy of 10 years with a three years' history of vomiting, believed to be functional. No organic or toxic cause had been found to explain the condition, and the x-ray examination demonstrated no obstruction, organic or spasmodic. A month previously the boy's condition was critical, the emaciation being extreme, his weight being only 27 lb. Following the passage of the stomach tube the vomiting had completely ceased, and his weight was now 41 lb.

Cases were shown also by Dr. BURROW, Mr. BRAITHWAITE, and Dr. W. H. ROWDEN.

EPILEPSY IN CHILDHOOD.

At a meeting of the Liverpool Medical Institution on January 14th Dr. DINGWALL FORDYCE read a short paper on epilepsies in childhood. He noted first the difficulties in early diagnosis of epilepsy, when the manifestations were of the nature of incomplete forms, such as visceral spasms. An epileptiform attack having occurred, the cause might in the first place (apart from diabetes or uraemia) be a gross intracranial abnormality, such as

birth trauma, infantile cerebral paralysis, or some forms of amentia. In the second place the attack might occur as a symptom of, or in conjunction with, primary amentia, and unassociated with gross intracranial abnormality. It was most important for prognosis to recognize whether or not amentia was present apart from the fits. He had recently in review 129 children of school age, reported as being sufferers from epilepsy, and of this number in 35 cases there was evidence of an organic cause or of primary amentia—that is, 18 cases of primary amentia, 10 cases of infantile cerebral paralysis, and 7 cases of birth trauma. The significance of such differentiation was shown by the figures for imbeciles. Of the 129 children, 32 were noted as imbeciles or probable imbeciles, and of this number 16 were cases of idiopathic epilepsy, 9 of primary amentia, 4 of infantile cerebral paralysis, and 3 of birth trauma—or, in other words, 16 out of 94 cases of idiopathic epilepsy and 16 out of 35 cases of organic lesion of the brain or primary amentia. In the third place cases might show no evidence of gross organic abnormality or of primary amentia. In this group were to be placed cases of spasmodophilia, infantile eclampsia, occasional fit or fits, pyknolepsy, and characteristic idiopathic epilepsy. In all the types of cases in this group the presence or absence of an essential or idiopathic epilepsy might be conjectural—for a time at least. Dr. Fordyce considered these last types in detail, with special reference to differential diagnosis and treatment.

Mr. K. W. MONSARRAT, in a paper on prolapse of the rectum, distinguished two types: the one in which the prolapse always commenced immediately above the anal canal, the prolapse increasing by the protrusion of the rectal wall progressively through the canal; the other in which the prolapse or invagination commenced high in the bowel, the primary invagination being of that segment where the pelvic colon became rectum. He considered the process in the former analogous to ileo-colic intussusception, in the latter to ileo-caecal intussusception. He described a series of cases of high rectal invagination without protrusion through the anus, and remarked that this invagination might have an acute onset and require an emergency operation. He described also the symptomatology of chronic cases and discussed the conditions of success in colopexy, which he considered a reliable remedy if these conditions were observed.

GAS AND OXYGEN ANAESTHESIA IN MAJOR SURGERY.

At a meeting of the Aberdeen Medico-Chirurgical Society on January 14th, Dr. J. F. CHRISTIE in the chair, Dr. J. ROSS MACKENZIE read a paper entitled "Some advantages of gas and oxygen anaesthesia in major surgery."

Dr. Mackenzie emphasized the fact that, although the technique of surgical operations had now reached a very high standard, there were still many unexplained cases of early post-operative mortality. He suggested that a toxic anaesthetic might be the deciding point against the recovery of a patient who was already suffering from a general toxæmia directly due to the disease. A new apparatus was described embodying a triple sight feed for the administration of nitrous oxide, oxygen, and carbon dioxide, with or without ether. Any combination and percentage of the gases could be obtained at will. He defined the advantages to the patient as operative and post-operative. The operative benefits were as follows: (1) ease of inhalation and induction; (2) safety of patient; (3) blood and circulatory apparatus unaffected; (4) anoxæmia absent with normal metabolism; (5) rebreathing with conservation of patient's own carbon dioxide; (6) de-etherization with rapid recovery. His methods of de-etherization of the patient were described in detail: first, by using the expired carbon dioxide; and secondly, by supplying through the apparatus pure carbon dioxide from a cylinder. He emphasized the benefits of rapid return to consciousness of the patient as being something of a triumph for gas and oxygen. The post-operative advantages were: (1) the marked relief to the patient from nausea, sickness, and

gastro-intestinal distension; (2) throughout the period of anaesthesia all the organs performed their normal functions; (3) the marked absence of chest complications. He put forward the suggestion that this form of anaesthesia acted as a protective against post-operative thrombosis and embolism. He thought that surgical shock was due more to a toxic anaesthetic, lack of oxygen, and loss of carbon dioxide than to operative trauma and loss of blood. In conclusion Dr. Mackenzie referred to the difficulty hitherto experienced in inducing anaesthesia with gas and oxygen in young children and infants, the explanation of this being the small tidal wave and the difficulty in expiring into a closed bag. This had been overcome by using a facepiece with a graduated expiration valve attached directly to the gas-bag.

Dr. A. OGSTON spoke of the safety and the approach to the ideal in gas and oxygen anaesthesia. He held that it had limitations, and required for success close co-operation between the surgeon and anaesthetist. Infiltration with novocain was essential for muscular relaxation. As regards surgical shock, he did not believe that the anaesthetic was the principal cause.

Mr. A. MITCHELL remarked that a great advance had been made in anaesthetizing children since the advent of gas and oxygen. He found it especially helpful in poorly nourished children where an operation of necessity had to be performed. He also appreciated the improvement in the atmosphere of the operating theatre as compared with open ether anaesthesia.

Mr. W. ANDERSON stated that a mixture of gas and oxygen was now recognized to be the best anaesthetic from the point of view of post-operative mortality in serious cases, and he did not see why it should not be used to reduce post-operative morbidity in all cases. Gentle handling of the tissues and infiltration with novocain were essential, and the surgeon and anaesthetist should share the responsibility for the patient's condition immediately following an operation.

FOREIGN BODY IN THE BRAIN.

At a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland on January 15th, the President, Mr. R. C. B. MAUNSELL, in the chair, Sir WILLIAM WHEELER showed a patient, aged 21, who had been wounded in the head in May, 1921.

During some street fighting the patient received what was then thought to be a small scalp wound above and to the right of the occipital protuberance; he was not detained in hospital. He heard at the time of his wound sounds of music in his ears, like a band with drums. A fortnight later, while smoking, he noticed a black dot in his right lateral field of vision. The speck moved medially, growing larger and becoming bright, until it appeared as a blinding light in the centre of his visual field; at this stage he became totally blind. He never lost consciousness, but he thought he saw men firing at him and that he was surrounded by companions. The attack was followed by headache and vomiting. These attacks lasted about twenty minutes, and recurred once or twice a month for four years. In the intervals he was well, and led an energetic life, but the constant appearance of the black spot made him feel morbid. There was no paralysis, motor or sensory; no alterations in the reflexes, and both fundi were normal; the fields of vision had not as yet been accurately examined. X-ray examinations disclosed that the nickel case of part of a conical bullet was lying in the base of the brain just behind the petrous portion of the temporal bone at the level of the eminence in the superior semicircular canal. To approach the bullet in a direct line it would have been necessary to open the skull behind the vertical line dividing the mastoid into equal parts. The direct route would have led through the sigmoid portion of the lateral sinus and some of the posterior branches of the middle meningeal artery. The skull was opened at a level above the location of the bullet, and when the meninges were divided a finger was passed under the temporal lobe in front of the cerebellum. After some difficulty a feeling of resistance was detected with the finger, and a pair of forceps was pushed through the temporal lobe in its direction. A mass about the size of an olive was located and enucleated; there appeared to be a line of cleavage between the mass and the brain substance. On removal, the "tumour" proved to be a mass of fibrous tissue encapsulating the conical point of the bullet. Before it could be extracted it

was necessary to nibble away bone towards the base of the skull, and the sigmoid portion of the lateral sinus was wounded; control of the bleeding was not difficult. During the removal some brain matter on the lateral surface of the temporal lobe was injured and removed. In bulk, the brain matter sacrificed was about the size of the tumour.

The after-history was uneventful; a month after the operation the patient appeared quite well; he had no recurrence of his previous attacks. On placing a model of the brain in position in a skull, and with the aid of x rays mapping out the exact position of the foreign body encapsuled in the fibrous mass, it appeared that the area involved was the association area between the visual area behind and the portion of the brain concerned with hearing in front.

Commenting on the case Sir William Wheeler said it was interesting to correlate these findings with the clinical history given by the patient. There were three points in the history: the sounds of band music on the day he was wounded, the distorted visual phenomena occurring on an average twice a month for over four years, and during each attack the reproduced impression of troops firing at him and of his being surrounded by his friends.

Dr. H. LAW remarked that when a foreign body had to be approached in a way which was not shown by x rays it was an extremely difficult operation, and he thought Sir William Wheeler was to be congratulated on the fact that he had only removed a piece of brain which could be spared. It was a pity that the field of vision in this case had not been tested before the operation, as comparison of the field of vision before and after operation would have been very interesting.

In reply to Dr. D. J. CANNON, Sir WILLIAM WHEELER said there had been no olfactory disturbances, and the bone had not been replaced; he had not tried to make an osteoplastic flap.

Infantilism due to Polyposis of the Colon.

Sir WILLIAM WHEELER showed lantern slides of a case of infantilism due to polyposis of the colon. The patient was a girl aged 16; she was stunted and dwarf-like, but not emaciated. Since early childhood she had suffered from diarrhoea and the passage of blood in the stools. Her height on admission to hospital was 4 ft. 5 in., and her weight 4 st. 13 lb. (the average normal height being 5 ft. 1 in.—weight 7 st. 8½ lb.). The breasts were undeveloped and there was an absence of axillary or pubic hair; mentally she was alert and normal. The speaker referred to the varieties of infantilism recorded in medical literature, and said that it was rational from the observations of the writers of these articles and the contributions of many other eminent physicians to conclude that polyposis of the colon might be the cause of infantilism, but that no other actual case was on record. The operative treatment in the present case consisted in removal of the polypi which were present in the rectum, and three months later the excision of a portion of the pelvic colon 8½ inches long by the operation of Mikulicz. Through the resulting colostomy opening more polypi could be felt with the finger, as high as the splenic flexure, and these were dealt with by capillaries containing emanations of radium inserted in the end of a rubber tube. When all signs of bleeding had disappeared the spur of the colostomy was crushed and the opening closed. Six months later the mother reported that the child was progressing well; she had grown 1 in. in ten months and had put on nearly a stone in weight. Sir William Wheeler referred to a second case of polyposis of the colon, in which he had performed complete colectomy. The colon in this case had lost all flexibility and on removal weighed 2½ lb.; the normal weight was only about 1 lb.

The PRESIDENT said that the case shown that evening reminded him of a case of multiple polyposis which Sir William Wheeler had shown at the Academy previously. He thought there must be some connexion between these two cases, although they were not identical. The case that evening looked to him like one he himself had seen recently, which was supposed to be tuberculous, in which the intestines were very much thickened, and which had been diagnosed as hyperplastic tuberculosis of the intestines. He

thought that Sir William Wheeler's case might be one of non-tuberculous ulceration.

Dr. H. LAW asked if the colon was smaller as a result of contraction of ulcerations. He thought that the lumen should have been contracted if there were a large number of ulcerations; to account for the formation of polypi by contraction he thought the lumen should have been large.

Dr. R. R. LEEFER had recently seen a case of polyposis of the intestine in a girl, aged 21, who had been sent to him certified as insane. She had a very fetid discharge from the rectum, and the whole intestine was a mass of small polypi. He asked whether this condition was associated with tuberculosis. In his case he had given injections of silver nitrate into the intestine, and the discharge had diminished appreciably.

Dr. C. J. MACAULEY said that it was not often that cases of polyposis of the colon were found in children. If the colonic condition was caused by want of absorption of foodstuffs, he wondered what the connexion was between the diarrhoea in this case and the want of growth. He asked if a barium enema and barium meal had been given. If that had been done it might have induced Sir William Wheeler to excise the whole colon. If infantilism was due to non-absorption by the colon, he did not think that good health in after-years could be expected in these cases by removal of the colon. It was strange to get infantilism of the whole body, and yet an overgrowth in the colon.

Dr. D. J. CANNON asked if a sugar tolerance test had been performed in this case, and if the symptoms of infantilism had decreased since the operation. He referred to a case of coeliac disease in which a necropsy had shown ulceration of the colon.

Sir WILLIAM WHEELER, in reply, said that he had had the patient x-rayed and had also had a proctoscopic examination carried out, but that neither of these had really given him any help. X rays showed a condition which was consistent with ulcerative colitis. All known cases of multiple polypi of the colon which were not treated by colectomy became malignant. In some cases, even in young children, when the colon had been removed it had been found to be already malignant. He did not think that polypi of the colon were associated with tuberculosis. He referred to the distribution of intestinal polypi in the rectum, where they could be felt and found, and said that he thought polypi in the colon, where they could not be felt, were probably much more common than was generally supposed. It seemed to him that the diarrhoea which occurred in colitis was in some way associated with infantilism. A sugar tolerance test had not been performed in this case.

Double Vestibulotomy.

Dr. H. LAW and Dr. G. BEWLEY showed a patient on whom Dr. Law had performed the operation of double vestibulotomy. A girl, aged 7, had developed acute supuration of the left middle ear, which appeared to be progressing favourably, but a week later she complained of headache and nausea, and had some convulsions. A tentative diagnosis of meningitis was made, but the cerebro-spinal fluid was found to be clear and sterile, though under considerable pressure. Shortly afterwards her pupils became unequal, the left being dilated; there was nystagmus to the right, and the eyes tended to deviate to the same side. Her knee-jerks were equal and normal; there was no ankle clonus and no Babinski's sign. Double vestibulotomy was done, and in a few hours the nystagmus, which before had been to the right, changed to the left, the pupils became equal, and the temperature fell to normal. Subsequently the child did not develop any signs of giddiness, and she was now practically well.

Dr. G. BEWLEY said that when he first saw the child he thought from the symptoms that it was a case of septic meningitis, following on ear trouble. He performed a lumbar puncture, under very much increased pressure, but found no signs of meningitis. This was done at 1 o'clock, and at 5 the reflexes had completely disappeared from the lessening of the pressure caused by the drawing off of the fluid. Before the operation the child was in a moribund state, and he did not think that she would live more than a few hours.

Reviews.

CLASSICAL STUDIES.

THIS group of essays by Professor J. W. MACKAIL, collected in a volume entitled *Classical Studies*,¹ sets out with a charming lucidity the meaning and value of the classics for us at the present day. He pleads that the classics should not be merely the study of the select few, but that, as is fitting in a democracy, they should be in widest commonality spread. Education should mean an initiation into the whole world of human knowledge and human activity. The classics form a large part of the best which has been said and thought in the world, and with this it is man's duty to try and make himself acquainted. Obviously everyone cannot be a Greek or Latin scholar, but everyone who gets as far as a secondary school might at least learn enough Latin to realize that there once existed a great civilization and a great literature, from which our own is directly derived; that, indeed, the classics are the very soil out of which the modern world has grown.

The main purport of the book is to show how large a place Greek and Roman civilization does still occupy in human life, and how that the literatures of Greece and Rome came nearer to perfection, both in their form and subject-matter, than any literature since then. The time has long gone by when anyone could, like Bacon, seriously think of taking all knowledge for his province; but the classics more than any other study help us to recapture that idea of the unity of learning, which is a symbol of the unity of life, and enables us to become, if but for a moment, in the words of Plato, the spectators of all time and all existence. This conception of the unity of all knowledge is easily lost amid the distracting multitude of optional subjects of study offered to us at the present day.

The essay on patriotism should be particularly helpful to the ordinary citizen. The stories of the old world Roman patriotism ("Then none was for a party, then all were for the State,") which group themselves around the names of Fabricius, Cincinnatus, and Regulus, show us a love of country springing out of a dignified sense of duty to the commonwealth. Reflections such as these would seem to have animated the Prime Minister in his recent (January 8th) inspiring address to the Classical Association. In this he pointed out that patriotism with the Romans was something innate and so sacred that it was never paraded, sought no reward, was taken for granted, and had no single word to express it. To dedicate the highest gifts to the public service was expected of every Roman citizen. Mr. Baldwin thinks that England has inherited much of the *pietas* and *gravitas* of ancient Rome, and still more might be said of those moral judgements which have guided men and women in England as in Rome, where moral instincts, rather than the clear reasoning of the Greeks, predominated.

Though Greek and Latin may no longer be spoken, they are certainly not dead languages, for they give expression to ideas which are still vital forces in the everyday life of man, strengthened as they have been lately by the new insight which has been given to them through historical, geographical, and archaeological studies.

Professor Mackail, himself a translator of Homer, is severe on translations, and maintains that even in prose the essential meaning of the original is but imperfectly and ineffectively given; at the same time he is of opinion that quite a small amount of Latin will enable a reader to appreciate the Latin poets. In our experience considerable acquaintance with a language is required before it is possible to enter into all the subtle associations and beauties clustering round particular words and phrases—before, in fact, we can appreciate, in the words of Tennyson, "All the charm of all the muses often flowering in a lovely word." Be this as it may, the book with its essays on the Odes of Horace and Virgil's Italy can be fully enjoyed by those in whose busy lives knowledge of Greek and Latin has grown rather rusty. R. O. MOON.

THE WORKING OF SANATORIUMS AND THE RESULTS.

ONE of the fullest descriptions of the sanatorium viewed in all its aspects is contained in Dr. L. GUINARD's *La Pratique des Sanatoriums*² (the working of sanatoriums), a book written in honour of the twentieth anniversary of the inauguration of Bligny. The sanatorium that he describes is a popular one under the control of a society in Paris, whose aim is to render treatment available to the poorer classes. It is divided into three portions, each capable of accommodating about 150 patients. This number the author considers critical; if it is exceeded, the difficulties of introducing the atmosphere of intimacy and familiarity that is so desirable are rendered almost insuperable. There is a long and detailed account of the structure and general arrangement of the buildings, illustrated by numerous figures and plates. One point of value is that a bathroom containing wash-basins and other toilet accessories is provided for every two wards. This obviates the necessity of a walk down a long corridor, an uncomfortable shave in a communal wash-house, redolent of steam, toothpaste, and other odours, filled with men who have risen late, and who in their anxiety to be in time for breakfast are only too ready to distribute water freely over any object, animate or inanimate, in their vicinity. The daily routine, the mode of cure, the food with an appetizing menu for each day of the week, the cost of upkeep, the direction, organization and administration, the general and special therapeutics, the heating, lighting, and disinfection—these and a host of other matters are related fully, not excepting a reproduction of the sixty-three rules for patients and of the twenty-five for the personnel.

We are interested to read of the high opinion in which the exercise treatment has come to be held. It is, of course, not practised according to its original rites, in which the dose of a hypothetical toxin to be absorbed by a patient could be regulated with nicety by his medical attendant, but is guided by that principle of truth which has been evolved from the work of Paterson and his successors—a principle taking account not only of the pulmonary lesion but of the whole mental and moral attitude of the patient.

As to the results we shall say little. Using the Turban classification, the author reports that the immediate effect of treatment was very good in 84 per cent. of Class I, in 14 per cent. of Class II, and in 0.4 per cent. of Class III. Figures for the after-history of the patients are so scarce as to be unworthy of notice. This failure to investigate the results of a method about which he can write a book of nearly 450 quarto pages we consider to be reprehensible on the part of the author. The sanatorium has been in existence for twenty years, and has treated 4,600 civil patients, and yet there is no record of value concerning the success of the treatment given. The figures that are reproduced are so few as to be quite useless, either for an estimation of this point or for a comparison with those of other countries. Surely the time has come when medical officers in responsible positions should realize that it is their duty in the interests of scientific medicine to collect their results and have them analysed by a reliable statistician. The public spends large sums of money on facilitating the execution of certain forms of treatment; it has the right to know their value. And we, who are interested from another point of view, are anxious to obtain a quantitative expression of this value. In many cases the data are available, but unless more attention is paid to the lead in this country of the Medical Research Council, and in the United States of the Metropolitan Life Assurance and other bodies, they will be utterly wasted. It is in problems such as the assessment of the results of sanatorium treatment of tuberculosis that the statistician is of inestimable value; without his aid the figures are meaningless.

Apart from this stricture we have little to say against the book. It is not likely to appeal to a wide circle, but among those interested in the planning, construction, and direction of sanatoriums it should be received with approval.

CHRONIC INFECTION OF THE JAWS.

THE object of Dr. STANLEY COLYER's little book on *Chronic Infection of the Jaws*¹ is not so much to discuss the relation of oral sepsis to general disease as to make a strong attempt to emphasize the close relation of these conditions. The author's presentment of the position as his experience has led him to see it is well constructed and logical. The book contains one of the best and most complete collections of pathological skiagrams we have yet seen, and, unlike many writers, he makes uniform use of *negative* films; this will be much to the advantage of the non-expert reader. One of the best and most useful chapters is on normal radiograms, though on the page depicting them he is careful to describe them as "comparatively" normal. Dr. Colyer brings out a most important point of interest to the medical practitioner as well as to the dental surgeon. He states that he is much impressed by the damage that the forcible regulation of children's teeth may bring about in the jaws. He shows that in some cases absorption of the apices of all or most of the teeth regulated occurs, accompanied by a general infection of the supporting tissues. This view is strongly and emphatically expressed, and we shall await with interest the opinions of expert orthodontists on it. Dr. Colyer concludes with an account of the various disease conditions believed to depend upon oral or chronic maxillary sepsis.

Although this book contains only 75 pages of text, its price is high (10s. 6d.), but this, no doubt, is due to the fact that it contains an unusually large number of full-page sets of skiagrams. Its one blemish is that it has no index.

THE WAR HISTORY OF THE VETERINARY SERVICES.

It is not necessary to go very far back in history to reach a time when there intervened between the medical and veterinary professions a considerable gulf, across which in recent years efforts have been made, with the progress of science, to build a bridge, and not without success, so that two years ago a Section of Comparative Medicine was instituted in the Royal Society of Medicine. The many points common to the two professions are exemplified in a remarkable degree in the history of the veterinary services during the great war, which was published not long ago in a single, bulky volume,² edited by Major-General Sir L. J. BLENKINSOP, a former Director-General of the Royal Army Veterinary Corps, and Lieut.-Colonel J. W. RAINEY. It demonstrates how closely the R.A.V.C. resembles the R.A.M.C. in its development, organization, and establishments for service in the field, and for the treatment and prevention of disease. The preparation of the volume was commenced in August, 1923, but the editors state that they were hampered by the absence of complete historical records, except in the case of the services on the Western Front. There was, however, no lack of statistical records, although only relatively few of these have been included in the volume. Reliance was placed to a great extent on contributions from individual officers, who kept records for their own interest, and, as these officers were dispersed throughout the empire, the production of the history was unavoidably delayed until last autumn. The result has justified the delay, for a history has been written that will prove to be of great value to the military as well as to the veterinary and medical services. The Royal Army Veterinary Corps served during the war in many lands, equalling in this respect the Royal Army Medical Corps; for apart from their work in the major campaigns, its units and personnel were employed in South and South-West Africa, East Africa, South Persia, North and South Russia, and with remount commissions in Canada, the United States of America, and Uruguay. The opening chapter describes the preparations for war from the time when the army veterinary services, as the

result of the experiences of the South African war, underwent a complete reorganization, similar to that of the army medical service at an earlier date. Previous to this reorganization the Army Veterinary Department consisted mainly of regimental veterinary officers, who worked with the aid of regimental farriers. In 1903 an Army Veterinary Corps of non-commissioned officers and men was created to assist the officers of the Army Veterinary Department, and eventually both officers and men were formed into one corps, just as the medical staff and Medical Staff Corps were amalgamated to form the Royal Army Medical Corps in 1898. Following on the establishment of a veterinary corps of officers and men, important steps were taken to form, for purposes of mobilization, veterinary hospitals, mobile veterinary sections (the equivalent of the R.A.M.C. field units), and base depots of veterinary stores. The number and capacity of these units expanded enormously during the progress of the war, and a number of new units were created, such as camel hospitals, camel mobile veterinary sections, field veterinary detachments, convalescent horse depots, veterinary examination stations, rhesus economizer detachments, army school for farriers, veterinary bacteriological laboratories, and reserve hospitals. The mere mention of these units shows how closely the organization and work of the veterinary resembled those of the medical services. A chapter on animal management has its counterpart in the work of preventive medicine during the war. As the authors of the volume remark, "animal management was looked upon at one time as entirely separate from veterinary science, just as in the dawn of human medicine there was little recognition of the essential connexion of the latter with the principles of hygiene." Animal management during the war became, in short, preventive veterinary medicine, and, as such, the chapter relating to it is of exceptional interest.

On the outbreak of war the personnel of the veterinary services consisted of 364 officers (of whom 169 were regulars, 148 territorial, and the remainder reserve or special reserve) and 322 other ranks. During the progress of the war 1,306 veterinary surgeons were given commissions, out of a total of 3,350 veterinary surgeons on the register. On July 1st, 1918, only 1,200 were left in civil practice in Great Britain, and, just as in the case of the medical services, it became a matter of extreme difficulty to decide on the relative claims of the War Office and of civil practice. The subordinate personnel reached a maximum strength, at one time, of 27,950, and altogether 41,755 passed through the ranks of the R.A.V.C. The casualties amongst the officers were: 4 killed in action, 11 died of wounds; 25 were wounded, 31 died of disease and 19 from other causes. Amongst other ranks 62 were killed in action and 358 died.

The volume as a whole is of great interest, containing as it does chapters on the veterinary services in the different areas of operations, on animal diseases, animal surgery, various statistics connected with these, and on the methods of collection, evacuation and transportation of sick and wounded animals from the front to the veterinary hospitals at the base, and the care of healthy animals on board ship. There are also chapters on voluntary aid and the work of the Royal Society for the Prevention of Cruelty to Animals, and on the disposal of carcasses, together with interesting extracts from the war diaries of veterinary officers. There are several useful appendices, charts, plans, diagrams, and photographs, and a good index. The volume is exceptionally well arranged, written in good, clear language, and is a fine record of the work which won for the Army Veterinary Corps its Royal title.

THE ESKIMOS OF LABRADOR.

DR. SAMUEL HUTTON's study of the health conditions and of the incidence of disease among the Eskimos of Labrador³ is the outcome of seven years' residence in close contact with the pure-blooded northern native population. The author has traversed a field of unique medical and sociological interest, and has rendered a significant service to medical science.

¹ *Chronic Infection of the Jaws*. By Stanley Colyer, M.D. London, D.M.R.E. London: H. K. Lewis and Co., Ltd. 1926. (Demy 8vo, pp. x + 75; 12 figures on 19 plates. 10s. 6d. net.)
² *History of the Great War based on Official Documents: Veterinary Services*. Edited by Major-General Sir L. J. Blenkinsop, K.C.B., D.S.O., and Lieut.-Colonel J. W. Rainey, C.B.E. London: H.M. Stationery Office, 1925. (Roy. 8vo, pp. x + 782; 17 charts, plans, and diagrams, and 15 photographs. 41 ls. net.)

³ *Health Conditions and Disease Incidence among the Eskimos of Labrador*. By Samuel King Hutton, M.D. Manchester, F.R.G.S., J. Locker, Ltd., The Wessex Press. 1925. (Cr. 4to, pp. 74. 6s.)

Dr. Hutton commences his interesting survey by a consideration of the effects on Eskimo health of environmental conditions, and at the outset discusses climate, food, and habits of life. The climate was fairly consistent, changing from a moderate summer to a prolonged and excessively cold winter. During the winter brief periods of thaw occurred which appeared to have an adverse influence on health. The main part of the Eskimo's diet is flesh or fish, the vegetable part being meagre. The flesh of the seal was eaten raw, dried, boiled, or rotten. Rotten seal flesh could be eaten with impunity by the pure-blooded Eskimo, but caused illness in Europeans and half-breeds. Trout and codfish were the principal fish foods. Cod-liver oil was in frequent use. Berries also were gathered and stored for winter use. The dietary was one rich in vitamins, with the possible exception of the antiscorbutic vitamin, which would be found in the berries.

The Eskimo life is one of activity and strain. Men and women alike showed marked power of withstanding fatigue. Very little clothing is worn considering the severity of the weather. The average Eskimo house is small, ill-ventilated, dirty, and ill-smelling. Tents used in the fishing time are more sanitary. Speaking broadly, the Eskimo constitution is weak and resisting power to disease is low. Old age sets in at 50, and in the years beyond 60 the Eskimo is aged and feeble. Careful records had been kept by the missionaries for more than a hundred years, and from these it seems that only in recent years have measles, small-pox, and enteric fever gained a footing.

A pandemic of rubella in 1906 ran a severe course, showing the powerful influence an otherwise mild disease might exert upon the native constitution. One of the most striking peculiarities of the Eskimo constitution was the great tendency to haemorrhage; epistaxis, menorrhagia, and haemoptysis all being common. This haemoptysis had to be distinguished from that due to pulmonary tuberculosis—a disease more frequently seen in Eskimos who had adopted a semi-European way of living. Other striking features were the tendency to debility of the heart and of the uterine muscle; for while in the Eskimo the voluntary muscles were in a state bordering on perfection, the involuntary muscles were weak. Typical scurvy was rare among the Eskimo, boils and abscesses common. A pandemic of a pustular skin eruption known as "kallak" followed the failure of the berry crop in 1904-5. This was almost certainly of scorbutic origin. The disease resembled scabies in appearance and distribution. The tendency to suppuration was pronounced. Nearly all cases of mumps ended in suppuration. Tuberculosis was apparently one of the diseases which had reached Labrador from other lands. It was not a widespread cause of death among the Eskimos, but ran markedly in certain families. A large proportion of Eskimo males had a small epigastric hernia. Other forms of hernia seemed to be extremely rare. No case of cancer in an Eskimo had been seen or heard of. In this connexion it might be noted that cookery holds a very secondary place in the preparation of food, most of it being eaten raw. Influenza was endemic on the Labrador coast. The gastric type was the most fatal. The commonest complication of the bronchial type was otitis media. Syphilis had recently become prevalent. Since its prevalence the birth rate had fallen to an extent which augured badly for the future of the race.

NOTES ON BOOKS.

MR. DODDS and Dr. LICKLEY, in their book *The Control of the Breath*,^a have sought to present a description of the mechanism of respiration, with an explanation of its action, so that the student of singing, elocution, or physical culture may have a basis upon which existing systems or authorities may be judged. Apparently writers on the subject, of equal celebrity, have expressed very divergent views, with the result that seven types of breathing have been taught by different instructors in singing, such as the abdominal, the thoracic, and varying types of inferior and lateral costal. Mr. Dodds and Dr. Lickley favour the combined abdominal

and thoracic type, which in their opinion gives the most complete chest expansion possible. The explanations of the respiratory act given by teachers of the combined abdominal and thoracic type have not been sufficiently convincing to dispose of the theories of other writers. In the present volume the structure and mode of action of the respiratory apparatus are described and diagrams and illustrations are reproduced from Cunningham's *Textbook of Anatomy*. The explanation of the second portion of the inspiratory act is, it is said, often unconvincing because writers have overlooked the fact that the diaphragm may act from more than one fixed point. It is held also that the function of the intercostal muscles is not respiratory but the maintenance of the form of the chest wall. The authors lay great stress on the development of the mechanism of quiet inspiration instead of the use of the muscles of forced inspiration for improving the breathing capacity for singing, believing that in this way breath capacity can easily be made to exceed the average usually given. The mechanism of quiet inspiration will, we are told, suffice for every voice user; but as it is with expired air that he actually works, his control of expired air must be absolute. And the power of the singer or speaker over his expiration lies in the strength and control of the abdominal muscles. The second part of the book contains directions for breathing exercises and for singing practice.

STENHOLM'S monograph on osteodystrophia fibrosa⁷ deals with the pathological conditions which von Recklinghausen embraced under the term "ostitis fibrosa." In this country it is customary to limit the name ostitis or osteitis fibrosa to one fairly definite disease, occurring usually as a local affection, less often in a generalized form; we also speak of it as fibrocystic disease of bone. On the Continent, on the other hand, the clinical aspect has, under the influence of von Recklinghausen, given way to histological considerations, and all diseases of bone in which a fibrous transformation of the marrow is a distinguishing feature are included under the term. It is therefore made to include osteitis deformans in its generalized and local forms, osteitis fibrosa, both generalized and local, certain cases of leontiasis ossea, possibly also myeloma and multiple myelomata, and the fibrous tumour-like formations met with in the lower animals. It would appear that these conditions are regarded as identical in so far as the underlying lesion is essentially identical, although the determining cause may differ in the several diseases. Thus Stenholm regards osteitis deformans as caused by arterio-sclerosis of the nutrient arteries of the bones, a condition which would not account for the osteitis fibrosa of young subjects. As usually understood (though etymologically this is incorrect) the word "osteitis" involves the notion of inflammation, and to this Stenholm objects. He considers that the primary change is a degeneration of the marrow, and that this is followed by a cirrhosis in a way similar to that which occurs in degenerations of the liver. He has therefore adopted the term "osteodystrophia" to indicate what, in his opinion, is the essential change. Several carefully studied cases are described in the monograph, which contains a very thorough discussion of the many difficult problems involved in the interpretation of these diseases. Full justice is done to the numerous authors who have studied the subject and as a summary of present views the book is of value. The essay, though the work of a Swede and published in Upsala, is printed in German in accordance with a custom which is less common than it was.

A second edition of a book on cellular electricity,⁸ by R. KELLER, contains an account of researches with vital staining which the author has carried on for many years in the hope of determining by means of selective staining the electrical potentials existing on cell surfaces and in cell contents. The factors governing the existence of electrical potentials in cells is discussed in the first part of the book, and the remainder consists of two equal portions describing experiments upon the staining of animal and vegetable tissues respectively. Among special forms of technique mentioned are the selective vital staining of plankton as elaborated by Gieckhorns, and Pétérff's methods for the micro-measurement of electric potentials in individual cells. This last represents a remarkable development exceeding in delicacy even the methods of micro-dissection and micro-injection as practised by Chambers and other American workers on single cells. The monograph as a whole deals with some of the most obscure problems of cytology, and the experimental results recorded are of great interest, even though there may not be any general agreement as to their exact significance.

^a *The Control of the Breath. An Elementary Manual for Singers and Speakers.* By George Dodds, Mus.B. Dunelm, and James Dunlop Lickley, M.D. London: H. Milford, Oxford University Press. 1925. (Roy. 8vo, pp. xii + 65; 25 figures. 6s. net.)

⁷ *Monographie anatomische Studien über die Osteodystrophia Fibrosa.* I. Lic., Fil. Mag. Norrl. Upsala: Almqvist and Söner, pp. 211; 18 figures.
⁸ *Zelle.* By Rudolf Keller. Second edition. Kittl. 1925. (Med. 8vo, pp. 320; 40 figures, 1.22.)

Dr. J. B. HURRY's book on poverty and its vicious circles,⁹ which we reviewed on September 24th, 1921 (p. 490), has now been translated into Italian. A Japanese edition appeared in 1921, and a French edition in 1924. The third English edition of vicious circles in disease,¹⁰ by the same author, has also been translated into Italian. We mentioned the Spanish edition on April 4th, 1925 (p. 664), and the Italian edition is very similar, but includes a full bibliographical appendix of the author's contributions about vicious circles to British periodicals.

The *Minutes of the Dental Board of the United Kingdom* and of its various committees for the year 1925, with twelve appendices,¹¹ have now been published in a bound volume. A list is given of the chairmen, officers, members, and trustees of the Board from 1921 to the end of 1925, and the reports of committees show the work that has been done in connexion with education, research, and dental health propaganda.

We have received a copy of *Fräulein Else*,¹² which is a translation by F. H. LYON of a work by ARTHUR SCHNITZLER. Schnitzler, like Sir A. Conan Doyle and Mr. Somerset Maugham, is one of the best known contemporary novelists and dramatists who have forsaken medicine for literature. The work, which is the first volume of a series known as "The Black and White Novelettes," is a piece of poignant psychology, describing the mental conflicts of a young girl who finally poisons herself with veronal.

⁹ *La Povertà ed i suoi Circoli Viziosi*. By Jamieson B. Hurry, M.A., M.D. With a preface by A. Graziani. Turin: Fratelli Bocca. 1926. (Demy 8vo, pp. xvi + 404; 1 plate.)

¹⁰ *I Circoli Viziosi in Patologia*. By Jamieson B. Hurry, M.A., M.D. With a preface by Professor Vittorio Ascoli. Rome: Luigi Pozzi. 1925. (6½ x 9½, pp. vi + 285; 24 figures, 1 plate.)

¹¹ *Minutes of the Dental Board of the United Kingdom and of its Various Committees for the Year 1925, with Twelve Appendices*. Vol. IV. London: Constable and Co., Ltd. 1925. (5s. net.)

¹² *Fräulein Else*. A novelette. By Arthur Schnitzler. Translated by F. H. Lyon. London: A. M. Philpot, Ltd. 1925. (Demy 8vo, pp. 149. 5s. net.)

PREPARATIONS AND APPLIANCES.

Ring Grip Forceps.

MR. N. BISHOP HARMAN, F.R.C.S. (London), writes: There is perhaps no more delicate manipulation in surgery than that required of the left hand of the ophthalmic surgeon when he picks up with forceps a minute strand of the iris preparatory to iridectomy. The tissue to be gripped is so slight, it is so often obscured by overlying tissues or blood, and the margin of safety in the movement of the iris is so narrow that the mastery of the forceps through which the actual movement has to be made should be as perfect as is possible: the instrument should be a part of the hand of the surgeon, as much part of it as ungual appendages to his fingers.

There are many excellent iris forceps in use. The main differences between them are in the set of the teeth of their extremities and in the size of the blades. But they all remain an instrument in the hand—they do not become part of the hand. In the forceps of which an illustration is given, instead of the customary solid side plates or bows with their serrations, fluting, or grooves designed to give some security of grip, the bows are expanded so as to allow a ring to be cut through the flat of each side. These rings are 8 mm. in diameter inside; their edges are square and not bevelled. They are cut in the positions into which the thumb or first finger naturally falls when holding the forceps. The pads of the extremities of the thumb and index finger fill these holes in the forceps, and at the moment that the teeth of the forceps engage the skin of the thumb or finger comes into contact so that the surgeon feels that the forceps are almost a part of the hand and that the points are just the extensions of the finger-tips. The sense of direction and security this gives is remarkable.

I have asked Messrs. John Weiss and Son, Ltd., 287, Oxford Street, London, to apply this new ring grip to iris forceps in the first instance, as these supply the most delicate test of its efficiency; but it is equally applicable and useful for any form of forceps.

Portable Illuminated Test Type.

Dr. W. R. Dunstan, deputy school medical officer, East Sussex, having experienced difficulty in refraction work owing to bad lighting, especially in the winter months, has had made for him by Messrs. F. Davidson and Co., 23, Great Portland Street, London, W.1, a portable illuminated test type. The contrivance consists of an opal tablet, carrying four lines of letters and forming one side of a box which measures six inches square and is one and three-quarter inches deep. It is illuminated from within by an electric lamp supplied by a battery attached to the box.

THE CRIMINAL RESPONSIBILITY OF THE INSANE.

LECTURE BY SIR THEODORE PIGGOTT.

A LECTURE on "Insanity, legal and medical," was delivered at University College, London, on January 20th, by Sir THEODORE PIGGOTT, I.C.S. (late Puisne Judge in the Allahabad High Court). The chair was taken by Sir ARCHIBALD GARROD (Regius Professor of Medicine at Oxford), and among those present was Lord Justice Atkin.

Sir THEODORE PIGGOTT said that lawyers—at any rate English lawyers—had never attempted to define insanity. To them the question was always one of the civil capacity or criminal responsibility of the individual in stated circumstances. On the medical side a definition had often been attempted, but the results were admittedly unsatisfactory. To the doctor what the lawyer called insanity was a form of nervous disease, and the doctor held that all nervous diseases, whether primary or secondary, congenital or acquired, should be regarded as one inseparable whole, of which so-called mental diseases comprised an inconsiderable proportion. It was only grudgingly that the medical profession would ever draw a line between hysteria, hypochondriasis, and delirium on the one hand, and mania, melancholia, stupor, and dementia on the other. The lecturer suggested as a short definition of insanity: "A symptom of nervous disease affecting the brain," and he had medical authority for the more elaborate definition: "Morbid conditions of the brain the results of defective formation or altered nutrition of its substance induced by local or general morbid processes and characterized especially by non-development, obliteration, impairment, or perversion of one or more of the psychical functions."

Historical Review of English Law.

In questions of civil practice the courts of justice seemed content to leave the matter in the hands of medical experts so long as these did not differ amongst themselves. It was with regard to criminal responsibility that conflict between the legal and medical points of view arose. The lecturer limited himself to those cases in which a plea of insanity was raised in defence of a person arraigned on a criminal charge. The fact that the success of this plea necessarily involved an order for indefinite detention in a criminal lunatic asylum explained why it was scarcely ever heard, outside works of fiction, except in cases of murder. To Coke belonged the credit of having definitely challenged the view of the older lawyers that insanity was not a defence in an attempt on the life of the sovereign; but Coke added a qualification so rigid that if it were acted upon it would sweep away the defence in the great majority of cases—namely, that insanity, in order to free an accused person from responsibility before the law, must be an absolute madness and a total deprivation of memory. It was Sir Matthew Hale who laid the foundations of the present law on the subject by recognizing the existence of what he called partial insanity, but the weak point in Hale's exposition was that he had not emancipated himself from the tendency to seek some artificial standard, which he suggested should be the mentality of a young adolescent, thereby confounding healthy immaturity with unhealthy maturity.

Sir Theodore Piggott then passed in review some notable criminal trials of the early part of the last century, and so came to the consideration of the trial of McNaghten for the murder of Mr. Drummond in 1843, and, arising out of that case, the answers given by fourteen out of the fifteen judges to the questions put to them by the House of Lords—answers which remained to this day the authoritative expression of the law of England on this subject. He drew attention to a latent ambiguity in one of these answers: "If the accused was conscious that the act was one which he ought not to do . . . he is punishable." But suppose the disease of the mind to take the form of a delusion that the person was under divine command to break the law of the land, or that circumstances had cast upon him the duty of saving others from intolerable ills

by taking the life of one, would it be said of him that he did what he was conscious he ought not to do? With regard to the taking of medical evidence, the answers were of some significance because they insisted upon the principle that the ultimate verdict of guilt or innocence was not to be taken by expert witnesses out of the hands of the jury. That was a protest of the law against the doctrine, found even in a book so generally sound as Sydney Smith's *Forensic Medicine* (1925) (unless, indeed, it was there put forward as a *reductio ad absurdum*), that rather than enlarge the scope of the rules so as to include deficient control it would be better to "throw over the whole principle of trial of the insane by jury and make insanity and irresponsibility coextensive."

Law as Codified in British India.

The lecturer glanced at the code in British India, where great pains had been taken to make the existing state of mind of the prisoner a matter for judicial determination. In India the prisoner could not be consigned to custody on anything corresponding to a Home Secretary's warrant, but only by order of the court, and in all cases of doubt the court had to try, as a preliminary issue in the case, the question whether the prisoner was competent to make his own defence. The custody to which he might be sent was not necessarily at the public expense; special power was given to consign into any custody approved by the court. In the Indian Evidence Act a brief section enacted the principle laid down in the M'Naghten rules that the burden of establishing the defence of insanity was on the accused, and for the substantive law recourse was had to the Indian penal code. It was laid down in Indian law that "nothing is an offence which is done by a person who at the time of doing it by reason of unsoundness of mind is incapable of knowing the nature of the act or that what he is doing is either wrong or contrary to law." This agreed with the second answer in the M'Naghten rules, except that it substituted the phrase "knowing the nature of the act" for the less definite phrase "knowing the nature and quality of the act," but such difficulties as had arisen in India had surrounded even this definition. The learned judges of the Calcutta High Court had laid it down that it was only unsoundness of mind materially impairing the cognitive faculties which could form an adequate defence.

"Moral Insanity" and "Irresistible Impulse."

Of all eminent lawyers, Sir James Fitzjames Stephen had come nearest to adopting the medical point of view. In his *Digest of Criminal Law* Stephen attempted a summary of the existing law on the subject in this country, and he found himself compelled to set forth alternative statements, in the one showing what was certainly settled law and in the other the law as he thought it really was and as he was sure it ought to be. The essential difference between the two lay in the suggested provision that it should be a defence if the accused was prevented by disease from controlling his own conduct. Stephen's argument brought out the essential points in the controversy between the medical and the prevalent legal view. The former demanded practical recognition of the existence of mental disease in which the moral faculties were more obviously diseased than the mental—the affections and will rather than the reason. "Moral insanity" was a phrase profoundly suspect to a lawyer. What was moral insanity but an unhealthy condition of the moral sense? To admit it as a defence was to open out for the benefit of the criminal too wide a prospect of possible immunity—a thing more dangerous in its practical consequences than immunity itself.

For the doctrine of irresistible impulse there was much more to be said. This had been widely recognized in criminal codes on the Continent, and it could be supported by the great authority of Stephen. Let it be remembered that what was being discussed was not an overwhelming impulse towards a certain line of conduct arising out of mental delusion as to existing facts; that was provided for

by the English law as it stood. The question was whether a man, clearly understanding what he was doing, was to be held exempt from responsibility on the sole ground that what he did was done under the impulse of a diseased mind which it was impossible for him to resist. But whatever Stephen might have imagined or desired, irresistible impulse as a defence against a charge of murder was not at present a part of the law of England. This was shown by the case of Ronald True (1922) and also in that of Alfred Kopsch (1925) in what was known as the Ken Wood murder. In the latter case the doctrine of irresistible impulse was laid before the court in its extremest form, fortified by the theories of up-to-date psychology as to the working of the subconscious mind. The lecturer here remarked that his own respect for the medical profession would prevent him from saying in his own words what had been long ago said by Stephen, whom he would quote: "Many people—and in particular many medical men—cannot be got to see the difference between an impulse which you cannot help feeling and an impulse which you cannot resist."

Is Amendment Required?

Was any change desirable in English practice? He had already expressed his preference for the Indian system, whereby the mental condition of the accused was invariably made a matter for determination by judicial authority. It seemed to him that the English system threw a burden upon the Home Secretary which he could not satisfactorily discharge. He thought that in all doubtful cases in which the defence of insanity could be raised with any hope of success the question whether or not the accused was disabled by disease from making his own defence should be tried out in advance before his defence was undertaken. It was dangerous to depart from the sound principle that a man who was incapacitated by mental disease from making his own defence should not be tried. He saw an illustration of this danger in the True case. True was found guilty of murder, and the appeal from his conviction failed, yet he was respited by the Secretary of State and was now in confinement as a criminal lunatic. Was it to be taken that the Secretary of State was giving effect on his own account and outside the ordinary law to Sir James Fitzjames Stephen's suggestion of a possible alternative verdict: "Guilty, but his power of self-control was diminished by insanity," or was the explanation to be sought in the nature of the medical evidence given at the trial? If the four doctors were right in deposing that the accused as he stood in the dock was certifiably insane it became a matter for serious doubt whether he ought to have been put on his trial in that condition.

What was involved in the concept of a true defence of insanity propounded as his own defence by an unhappy man who had taken human life at a time when his reason was dethroned by disease? One powerful consideration was suggested. According to what the lecturer understood to be the best medical opinion on the subject, a sufferer from such an impulse, succumbing to it after desperate resistance, would be overwhelmed with horror and remorse as soon as the impulse had spent itself. The abiding element in this horror would be a dread lest a return of the impulse should lead to a repetition of the crime. Would not the wretched man regard his own condemnation and execution as being entirely just and desirable as a reparation for a wrong done to society, as a possible deterrent in the future to some other sufferer, and as the one certain guarantee against a recurrence of the same ghastly experience for himself? In any conceivable case in which irresistible impulse would be a true defence it would never be raised at all; it would be precluded by the prisoner's plea of "Guilty." In conclusion the lecturer fell back upon the words of the Solicitor-General (Sir William Follett) in the M'Naghten case, when he said that the public safety required that the law should stand firm. The clemency of the Crown would cover extreme cases. It was too dangerous to unfasten a door through which many would seek to pass whose self-control had been impaired only by persistent indulgence of base passions and the gratification of evil desires.

THE HEALTH OF THE ARMY.

ANNUAL REPORT FOR 1923.

THE annual report on the health of the army for 1923,¹ just published, has followed somewhat closely on the heels of the report for 1922, and, from the Director-General's statement in submitting it, the report for 1924 should also be well on its way. This is all to the good, and to the credit of Sir William Leishman's efforts to expedite the issue of these annual reports. In the 1923 report new features have been introduced, and information formerly distributed under a variety of headings has been collected, analysed, and presented, as a general survey of the more important diseases from both an individual and economic standpoint.

There was a general decline in disease incidence in 1923 as compared with the two previous years. The admission rate for officers was 286.9 per 1,000 of strength, as compared with 298.3 in 1922 and 374.2 in 1921; the death rate was 3.93, as compared with 4.48 and 5.90. Among other ranks the admission and death rates in 1923 were 484.0 and 2.84 per 1,000 respectively, as compared with admission rates of 515.8 in 1922 and 649.9 in 1921, and death rates of 3.22 and 4.20. The most prevalent disease in both officers and men was malaria. Among the former the next most prevalent disease was inflammation of the areolar tissues, and among the latter venereal diseases. Malaria, sandfly fever, inflammation of the tonsils, and dysentery were slightly in excess of the ratios for the previous years; but a considerable decrease occurred in influenza and venereal diseases, the admission rate of the latter being 56.4 per 1,000, as compared with 70.7 in 1922 for the whole army. Several pages of the report are devoted to short summaries of information regarding individual diseases, and some interesting facts are recorded. Dysentery and diarrhoea together accounted for an admission rate of 219.6 per 1,000 of strength in Iraq, but only 33.7 in Turkey and 28.2 in Egypt. Nearly all the cases in Iraq were amoebic, whereas only one of the cases in Turkey was of that type; in Egypt 35 out of 64 cases were amoebic. This bears out much of what has previously been recorded in connexion with the geographical distribution of amoebic and bacillary dysentery.

The remarkable change in the picture of the incidence of enteric fever in the army is again noticeable. Including the paratyphoid groups, only 1.1 cases were recorded per 1,000 of troops. The admission rate in India alone, where the disease used to be most prevalent, fell from 3.0 in 1922 to 2.3 in 1923, the same as in 1913, when the ratio was the lowest on record. The inoculation rate was 95.1 per cent. in India and about 90 for the whole army.

In the notes on malaria it is remarked that the judicious use of arsenic alternately with quinine proved the most efficacious method of preventing relapses in chronic cases. Small-pox was very prevalent among the civil population in the United Kingdom, but no case occurred in the army. In India there were 14 cases, 3 on board ship returning from there, and 13 in Turkey. Nothing, however, is mentioned regarding the state of vaccination in these cases.

Figures are given in connexion with age and service incidence of tuberculosis, but they are somewhat confusing. Fifty-three per cent. of the cases occurred in the first five years of service and 65 per cent. between the ages of 18 and 25, but it is difficult to understand the conclusion drawn that a proportion of the cases could be eliminated by more careful recruiting; for the greatest incidence actually occurred among men with five to ten years' service, and there was a consistently high ratio, double that of the whole army, among men with over ten years' service, and up to the age group 35 to 40 years. As in the previous year, the incidence of venereal diseases was highest in the army on the Rhine, when the ratio of admissions was 136.3 per 1,000. In the United Kingdom it was as low as 27.4, and in other oversea commands 96.9 per 1,000.

There is an interesting statement under the heading of

flat-foot. Recruits with high arched insteps, it is stated, are liable to acquire this affection when they put on weight and are made to carry equipment before the supporting muscles are properly trained to bear the extra weight. Any good that may have resulted from weeks of treatment of such cases by special boots may be undone in an hour by reverting to gymnasium shoes!

In the remaining pages of the report the usual statistical tables are given for the army as a whole, and for each command. The average strength of officers was 10,423, of other ranks 181,621, of women on the married roll 16,876, and of children 27,052. The strength of the troops in the United Kingdom was 88,468, in India 63,139, in Turkey 11,560 (entirely withdrawn in September), in Egypt and Palestine 10,482, in the Rhine Command 8,214, and in other oversea commands less than 2,000. The British troops in Iraq, numbering 1,935, were under the administration of the Air Ministry. It was by far the most unhealthy command, with an admission, death, and invaliding rate of 1,289.2, 10.8, and 51.39 per 1,000 respectively. Turkey showed the next highest rates among commands with strength of over 1,000—namely, 635.5, 2.85, and 16.08 respectively. The Iraq figures are also greatly in excess of the figures for 1922 and 1921, when the admission rates were 700.8 and 894.8; the death rates 4.45 and 10.74, and the invaliding rates 37.43 and 33.18 respectively. This marked difference may be due to the statistical fluctuation arising from the smaller strength in 1923. The general statistical tables are followed by an account of the work of the special departments of medicine, surgery (including x-ray departments, massage, and electro-therapeutics), hygiene, pathology, dentistry, and medical examination of recruits. In a short review it is not possible to note the many interesting features of the work of these departments.

The records of the medical and surgical departments are new features in the report. Their interest, as well as that of the other departments, lies in the evidence they present of the wide extent, activity, and opportunities of professional work and scientific research in the army. In future reports it is understood that still greater prominence will be given to this aspect of the army medical service, and should go far to remove the impression among newly qualified men that the army is not a good field for the exercise of their profession. The report for 1923 is bulkier than that of 1922, and the price has gone up sixpence, but this is chiefly due to its being printed in larger type.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee forty-one cases were considered, and £451 18s. voted to thirty-two applicants. The following are notes on some of the cases relieved.

Widow, aged 60, of M.D. Edlin, who died in 1905. She has two children—a daughter, aged 26, who is a dispenser earning £3 a week, but not living at home, and a son, aged 25, who has defective hearing, is unable to get employment, and lives with applicant. Only income £29 per annum and £10 10s. received from letting rooms. Has applied for the Epsom pension. No rent, but rates amount to £9 a year. Voted £12 in twelve monthly instalments.

Widow, aged 59, of M.R.C.S. who practised in England and then went to New Zealand for eight years, and died in 1905. The applicant and her daughter lived on the £3,000 he left, but £1,700 of this was lost by bad investments. The daughter, who is not strong, is nursing in a sanatorium, receiving £2 10s. a month. The applicant has had to give up nursing at present owing to bad health. Voted £10.

M.R.C.S. Eng., aged 71, unmarried, is unable to obtain employment as a locum tenens owing to age, and suffers from rheumatism. He has been in receipt of the old age pension for the past twelve months; board and lodging cost him 25s. a week. Voted £50 in twelve monthly instalments.

M.R.C.S. Eng., aged 54, who up to 1923 had a practice in the Midlands and afterwards acted as locum tenens. He has been unable to get work, and since Christmas, 1923, has lived on savings and been helped by the charity of friends. He had to apply recently to the guardians. The rent of his room is 12s. 6d. a week. Voted £9.

Widow, aged 68, of M.R.C.S. Eng. who died in 1890, has maintained herself ever since, and it is only owing to an accident which happened last August that she has now applied for assistance. She was married for nine weeks. Her only income is an Epsom pension of £20, and 8s. a week from her married daughter; her rent amounts to 10s. a week. Voted £18 in twelve monthly instalments.

Daughter, aged 52, of L.R.C.P. who died in 1883, is unable to earn her own living as she has to look after her mother, aged 85. The mother has the old age pension, an annuity from the Fund, and is assisted by the Guild. The rent is paid by applicant's sister. Voted £18 in twelve monthly instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos Street, Cavendish Square, W.1.

SATURDAY, JANUARY 30TH, 1926.

HYPERPIESIA.

IN the early seventies of the last century Clifford Allbutt and Frederick Mahomed were working, together with Burdon-Sanderson, on arterial pressure, attempting its measurement with the sphygmograph, and in the following years Mahomed published a series of papers dealing with the relationship of high arterial pressure to renal disease. In his last paper,¹ entitled "Chronic Bright's disease without albuminuria," Mahomed endeavoured to show that a high arterial pressure was not necessarily the consequence, but was in fact often the antecedent of renal disease; that it might occur in youth and mark out the individual as a future victim of Bright's disease; and that it produced a series of generalized vascular changes accompanied by hypertrophy of the left ventricle, all of which might or might not be followed by renal disease. By Mahomed's early death English medicine lost a brilliant investigator of relentless energy, and with the gradual recognition of the fallacies involved in sphygmographic records as measurements of arterial tension much of the clinical observation that accompanied them was neglected and forgotten. Allbutt, however, persisted, and taking advantage of every improvement in our methods of estimating arterial pressure, and with an ever-widening clinical experience, gradually brought into focus the clinical picture which he termed "hyperpiesia."

It is now pretty generally admitted that there is a disease, not necessarily associated with demonstrable disease of the kidney, of which the cardinal symptom is a persistently raised arterial pressure, frequently accompanied by thickened arteries and cardiac hypertrophy. If as a clinical entity hyperpiesia is now generally recognized, yet the etiology and the pathological basis on which it rests are still largely matters of speculation and hypothesis; and it was with these aspects that the speakers were mainly concerned at the discussion which was held at the Annual Meeting of the British Medical Association last summer,² and again at a recent discussion at the Royal Society of Medicine, a report of which appears in our pages this week (p. 190). So far as the morbid anatomy is concerned we have, indeed, some definite knowledge, for as a result of a careful study of the smaller arteries and arterioles Dr. Geoffrey Evans³ has established in diffuse hyperplastic sclerosis a narrowing of the lumen of these vessels by an intimal thickening which he finds constantly present. There is, however, no clear evidence whether the hyperpiesia or the vascular proliferation is the first to occur, or whether, as Dr. Evans himself suggests, they are both the simultaneous result of some common pathogenic agent. The search for such a pathogenic agent of a pressor type has occupied many workers, but no substance has yet been found that fully satisfies the conditions. Dr. Batty Shaw,⁴ whose monograph details a long and careful consideration of the subject both on the clinical and experimental side, has suggested that, in some cases at least, hyperpiesia may be

produced by the escape of renin into the circulation from diseased kidneys, but no positive evidence of this is as yet available.

It had thus become obvious that inquiry along other lines was essential, and Lord Dawson, who opened both the discussions referred to, has endeavoured to obtain further light by tracing the condition from an early stage. In an inquiry as to the occurrence of raised arterial pressure in a series of school children, Lord Dawson found that out of 650 children examined 8 per cent. showed a systolic blood pressure above 130, and in classes working for a higher examination involving some anxiety and strain the incidence of an abnormally high blood pressure was two and a half times as high as in other classes; this, he claims, is evidence, not of a degenerative process, but of an inborn peculiarity of function in virtue of which the arterioles of such individuals are oversusceptible to what for most people are normal stimuli; and he puts forward the view that the overtone so produced may increase and persist, to be followed gradually as time passes by vascular thickening and cardiac hypertrophy. This is an alluring thesis, and those who remember Dr. F. L. Golla's⁵ fascinating experiments with mental arithmetic by the fireside will not deny its importance. Professor F. R. Fraser thinks it a mistake to look for one cause common to all cases, and suggests rather that the condition may be due to one or more of a number of causes in different individuals; and in emphasizing the need for a careful investigation of the early history at the onset of the raised pressure he urges the more extended use of the sphygmomanometer and the importance of registering the diastolic as well as the systolic pressure. The need for a more general use of the sphygmomanometer in general practice was also urged very strongly by Dr. Otto May in his presidential address to the Assurance Medical Society, of which we recently published a report.⁶ But here a certain difficulty comes in, for although there is general agreement that in order to get the full value from blood-pressure readings a measurement of the diastolic as well as of the systolic pressure must be made, there are unfortunately a number of methods of selecting the moment chosen for taking the diastolic reading; and Dr. R. A. Young observed on the same occasion that, although he knew what he himself meant by the diastolic pressure, he did not know what anyone else meant. Doubtless this difficulty will disappear with further experience, and the insurance companies are doing good service to medicine in encouraging a much more common use of the sphygmomanometer in general practice.

Dr. McCrae suggested at Bath that the elucidation of the problems of hyperpiesia lay largely in the hands of the general practitioner, and it is this point that we wish to emphasize particularly here. Some years before the war there was at one of the summer exhibitions of the Royal Academy the portrait bust of a medical man in which the artist had portrayed his subject in an attitude of rapt attention, trying, as the legend said, to catch the moment "when that which drew from out the boundless deep turns again home"; or, in more prosaic language, seeking for the first beginnings of disease. In no disease is this search more essential than in hyperpiesia, whether we consider the interest of the patient or the wide aspect of pathology, and in the main it is possible only for those who can watch their patients in what we are apt to call, perhaps somewhat thoughtlessly, the minor

upsets of a healthy life. When once the condition of hyperpiesia is fully established we cannot hope to repair the structural damage, and the chief therapeutic measure can only be to regulate the manner of life in accordance with the capacity of the patient; but if it be possible to detect the future victim while still in the potential stage we may hope that Lord Dawson's vision may be realized, and that hyperpiesia will pass into the beneficent realm of preventive medicine.

MANIPULATIVE SURGERY.

THE discussion on manipulative surgery at the Medical Society of London last Monday, of which a report is published at page 187, was of great interest and should be of much value to the profession, and if an epitome of it could be conveyed to the general public through the lay press it would go far towards disabusing the minds of newspaper readers of the delusions which now possess them, and which are so sedulously propagated even by journals of the greatest eminence. Herein lies the great difficulty, for while leading daily papers are too eager to give all the glory of large type on the leader page to false statements by popular writers of fiction and others, it appears that no room can be found for the refutation of such misstatements even when they are guaranteed by the signatures of responsible and highly respected officials.

If we were to believe the daily papers we should have to conclude that manipulative surgery is the exclusive preserve of the irregular practitioner, whereas it is practised, and practised with success, by a far greater number of qualified practitioners than of bonesetters. When the irregular practitioner succeeds with a case in which a qualified surgeon has failed, the fact is widely advertised by the patient and others. When, however, the converse happens—as it does much more often—nothing is heard of it, for the patient is not proud of his excursion into the realms of unqualified practice and the surgeon does not advertise his successes. In the last ten or twelve years there has been a great development in the theory and practice of orthopaedic surgery, and the number of surgeons who practise it has been largely increased. They were originally concerned mainly with deformities and diseases of bones and joints in children—whence the name, now rather out of date; but adults have benefited by the growth of knowledge, and one result is that specially skilled manipulative treatment by qualified surgeons is far more generally available than it was before the war. This being the true position, it may be asked why it is that such a campaign of detraction of the surgeon and glorification of the bonesetter has been carried on. It was referred to by several of the speakers in the debate as a press “stunt,” and such in a great measure it no doubt is; but is it not possible that at the back of it all is the apprehension by the bonesetter and the osteopath that the regular practitioner is curing more and more of the cases which used to go to him, and that the instinct of self-preservation has really inspired this desperate counter-attack, in which professional humorists and lovers of paradox have delighted to take part? By what means the lay press has been so strangely influenced we do not know, but it might be found that personal experience or the knowledge of some isolated case may have influenced the directors of the policy of the newspapers in question.

In their excellent addresses opening the discussion on Monday Mr. Elmslie and Mr. Rowley Bristow admirably described the class of cases on which

the bonesetters thrive, and also the methods employed by orthopaedic surgeons; they expressed the opinion that even more time and care might wisely be devoted to teaching students the principles and methods by which derangements of joints and muscles are best treated. In this connexion Sir Holburt Waring reminded the meeting that the General Medical Council had some time ago recommended the licensing bodies to pay attention to the teaching of what it somewhat unfortunately described as mechano-therapeutics. The surgeon, apart from the fact that he is trained in diagnosis, has one great advantage over the bonesetter which the lay public does not properly appreciate: he is able in the last resort, and practically without risk, to lay open the affected joint or to expose the painful bone, and so to treat the evil radically. There is, however, one class of case in which the irregular practitioner has often been successful, and which was referred to by more than one of the general practitioners whose contributions to the debate were so valuable. We refer to cases of backache or low back pain, due often to some small adhesion in the erector spinae, which can be broken down only by vigorous passive movement, but in which such breaking down works an instantaneous cure. There may be truth in the suggestion that such methods should be more systematically taught to students and followed by practitioners, though we are aware that in some centres this teaching is very far from being neglected. Dr. Des Voeux made a useful contribution to the discussion when he spoke of those cases, often described by the patient as neuritis, in which the original cause was some small and perhaps forgotten injury to a joint at a distance from the later site of pain, cases which may be relieved instantaneously by the breaking down of some small and hitherto overlooked adhesion in the joint at fault.

The debate seemed at one time likely to drift into a revival of the old controversy between specialists and general surgeons. Mr. J. E. H. Roberts, who is himself skilled in orthopaedic surgery, protested against the restriction of manipulative surgery to orthopaedic specialists; and he is not alone in taking this line. As Mr. Elmslie pointed out, nobody, least of all the orthopaedic surgeon, wishes to prevent the general surgeon or the general practitioner from carrying out manipulative methods. His desire is, on the contrary, that the general surgeon should devote much more of his time and attention than he does at present to the injuries and disabilities on which the bonesetter thrives, and that he should teach in the ward and in the out-patient department the importance of those conditions and of this line of treatment. If, however, his predilections do not lead the general surgeon to do this, or the manifold and overwhelming claims upon his time made by emergency operations, especially on the abdomen, stand in his way, then it may be well for every teaching school to consider the advisability of establishing an orthopaedic unit constituted on some such plan as that sketched by Sir Robert Jones in the address on fractures published in our columns last year.¹ This suggestion was made, and is here revived, not as a defence for the regular profession against bonesetters and osteopaths, but in the interest of the public, and especially of the industrial worker, who would be the first and chief sufferer were the scheme for a special register of inferior manipulative practitioners, which it is rumoured has seduced a considerable number of members of Parliament, carried into effect.

¹ BRITISH MEDICAL JOURNAL, 1925, vol. 1, p. 903.

WHOLESALE PATHOLOGY.

PATHOLOGICAL investigations of clinical material are an essential to good medical work. The examination of urine, faeces, blood, lymph, discharges, and excised tissues are matters of daily necessity. In many cases exact diagnosis cannot be obtained without these examinations; and the omission of them in such cases would be blameworthy. Treatment often cannot be carried out without such examinations; for many therapeutic measures can only be controlled through periodic pathological examinations. The busier and more experienced the private medical practitioner the more will the need for these examinations become manifest, and the less will he be able to acquire the necessary skill or find the time to make them for himself. Further, the technical elaboration of many modern pathological investigations is such that a practitioner, with rare exceptions, will not himself attempt them as part of his regular clinical work, but must rely upon the assistance of medical colleagues who devote themselves to what is commonly known as clinical pathology.

Given clinical pathology as a legitimate and most necessary medical specialty, the point arises: How is this work to be done most efficiently and in the best interest of the patient? Will the pathologist do his work best in his own laboratory, with his own colleagues and assistants, and in personal contact with his clinical colleagues who come to him for aid in the diagnosis of the disease of their patients? Or will the pathologist do his work best as the employee of some one or other of the many bodies which maintain pathological laboratories—universities, hospitals, sanitary authorities, commercial firms, and the like—so that he works behind the screen of some impersonal concern? To put the matter in another way, should the pathologist be a colleague of the clinician, or a veiled oracle whose methods and the quality of whose work may be unknown or very little known?

At the present time both of these two lines of pathological practice are being pursued. There is a growing body of private pathologists whose work is highly valued by their clinical colleagues. There are also many university and hospital laboratories of high standing. And there is a rapidly increasing exploitation of the work by numbers of "clinical laboratories" established and maintained by commercial companies, institutes, and even hospital and sanitary authorities. The activity of the latter class of laboratories is manifest. The private practitioner receives through the post numberless offers of service from them, with schedules of tests and equipment and scales of fees. These offers, brought to our doors as it were, often look, upon the face of them, somewhat attractive. The necessary collecting and packing equipment is at hand, the material has but to be posted, and a telegraphic or postal report is received. It is as easy as a penny-in-the-slot machine.

Easy it is. But the question arises, Is it good pathology? Do the practitioner and the patient get the same thing as can be gained by even the briefest communication or consultation between two persons who know each other and their work? Experience seems to suggest that they do not. Urine from an unknown patient, collected in an unknown manner, is examined. What value, in a critical case, can be attached to a report thereon? Maybe it swarms with *B. coli communis*: is that an indication for vaccine treatment, or merely a sign of defective collection? Will a negative Wassermann reaction on a specimen of blood be of value apart from knowledge of the treat-

ment being given, or without consideration of the possible need for examination of cerebro-spinal fluid? A septic tooth may be so dispatched that the finding of streptococci is inevitable: will a vaccine be justified? This is a point touched upon by Dr. Mackey in his "common sense" paper read to the Coventry Division and published elsewhere in this issue. Again, what pathologist can, and what worker of experience will, give an opinion on a snippet of "new growth" presented bare of information; and what value can be attached to an opinion given under such conditions? Common examples such as these show that personal contact between clinician and pathologist is imperative if findings are to be of real service, and not, possibly, a source of danger to the patient. Only by such contact can the clinician know the limitations of the pathologist, and how specimens must be presented. Only by such contact will the pathologist be a "clinical" pathologist and free from the vice of *ex cathedra* dogmatism.

There are other sides to the problem. Commercial firms and "institutes" freely advertise the facilities they offer, and the manner in which these firms and institutes advertise their facilities is alleged to be a hardship to the private pathologist and to handicap him severely. The private practitioner, be he clinician or pathologist, cannot and will not resort to such practices, so that he is overshadowed by the impersonal advertising laboratories. If the work of these advertising laboratories be done by registered medical practitioners it may even be argued that these practitioners are involved in what is something like a breach of ethics in lending themselves to such practices. Added point has been given to this problem by the recent acclamation in the lay press of the establishment of a clinical laboratory by a hospital in London, which thus becomes a new competitor in the field for all cases, whether patients of the hospital or not; and of a provincial sanitary authority which has advertised to the practitioners in its area that it is prepared to do all such work.

It is sometimes good to take a critical survey of new developments in medicine and try to ascertain the effects thereof, whether good or bad. The arrangements under which the routine work of clinical pathology is carried out need such a critical survey; and the Council of the British Medical Association has appointed a Special Pathological Committee to investigate and advise it upon the present position. The task will not be easy, but it is one that must be faced. We may hope to obtain some concerted opinion at no distant date.

THE PREVENTION OF MENTAL DEFICIENCY.

It is in general unwise for eminent persons to make public pronouncements upon subjects with which they are not specially acquainted. One reason is that they may speedily be shown to be in error by those having a deeper first-hand knowledge of the subject. Another and more important objection is that the very eminence of the persons making the pronouncement is apt to mislead the public, who take them as having authority in fields where in fact they have little. These disadvantages are illustrated by two letters which appeared in the *Times* last week. The first letter, signed by a number of well known physicians and surgeons (including one laryngologist), was an appeal for the sterilization of all mentally defective persons, with a view to stamping out the condition in a more effective and more economical way than by segregation in institutions. The second letter, which seemed to be a complete refutation of this thesis, was written on behalf of the Council and

the Medical Committee of the Central Association for Mental Welfare. This communication refers to facts which are now beyond dispute, but which, as the earlier letter reveals, are not as well known, even to the medical profession, as they should be. Yet the British Medical Association and the JOURNAL have on a number of occasions drawn attention to these facts. At the Annual Meeting in Portsmouth in 1923 the whole-day session of the Section of Medical Sociology was devoted to this subject (BRITISH MEDICAL JOURNAL, August 11th, 1923, pp. 219-234), and at Bradford in the following year one session of the Section of Diseases of Children was given to that very aspect of the matter which is the subject of these letters (BRITISH MEDICAL JOURNAL, August 23rd, 1924, pp. 316-332). Further, an important pamphlet on "Sterilization and mental deficiency," published in 1923 by the Central Association for Mental Welfare, was noticed in our columns at the time, and in a leading article on "Mental defectives in New Zealand" (September 12th, 1925, p. 486) we again drew attention to the conclusions therein reached. Mental deficiency, of course, is distinguished from mental disorder or disease and from mental degeneration or infirmity by being due to a defect in the germ which prevents the proper development of mental powers to within the limits of the normal. It is therefore a primary amentia—an innate incapacity for normal development—though there is a minority of similar cases where an early arrest of normal development is due to some adverse factor operating directly on the embryo or young child. It follows, therefore, that mental defect is a lifelong incapacity in some degree, and that it is usually of an inherited and inheritable nature. But this does not justify the two fundamental statements made in the earlier *Times* letter: (a) "If propagation by the mentally deficient be stopped their numbers will rapidly decrease"; (b) "With few rare exceptions the feeble-minded remain as they are no matter what is done for them." It is true that "the offspring of mental defectives are themselves mostly mentally deficient," but elementary logic reminds us that the converse of a true proposition is not itself necessarily true. It is very far from true that mentally deficient children are mostly the offspring of mentally deficient parents; in fact, only a small minority of them are the offspring of such parents. The inheritance, whatever its exact nature, is usually derived from parents who appear to be normal, although many of them may be "carriers" of the germinal defect, or who are in some way mentally unstable, but not certifiable defectives. It follows that even were all certifiable defectives sterilized mental deficiency would not be eradicated, and its prevention would be effected only to a relatively insignificant extent. Moreover, sterilization alone (not castration) would leave the defectives free to pursue such antisocial conduct, including promiscuous sexual intercourse, to which most such persons are prone in the absence of institutional care, with its consequences in the matter of venereal disease. It might even lead to an increase of such evils. The other serious statement quoted above is also incorrect. The signatories allow that "everything possible should be done to render the lives of these defectives as happy as possible," and it may be agreed that this is almost all that can be done with the lower-grade feeble-minded as with the imbecile and idiot, and that public expenditure to this end should be strictly limited. The case of the moron, or higher-grade feeble-minded person, is different. Very much can be done to improve even the mental powers of such children, so that they reach the highest possible development of which they are capable, through an education adapted to their condition. The actual results of such an education are, indeed, surprising and most gratifying. After this care not all higher-grade mental defectives are socially defective, though a lack of self-control and of foresight persists to an abnormal degree.

Many, with a relatively small amount of supervision, can do useful and self-supporting work in the lower ranks of industry, though for the most part, even on leaving the special school, morons are the better for institutional control, which is made more beneficial to them, happier for all concerned with them, and much less expensive for those who support them, by their previous training. To suggest the routine sterilization of all these higher-grade defectives as they leave the special school implies misapprehension of the circumstances, for it is safe to say that the public opinion of this country, with the facts put before it, would never tolerate such a procedure.

INFLAMMABLE MIXTURES OF ETHER AND OXYGEN.

IN our issue of October 17th, 1925 (p. 713), we gave a brief account of the medical evidence at an inquest on the body of a lad who died in consequence of an explosion in his mouth during an operation for fractured jaw. Ether and oxygen was the anaesthetic, and warm air was applied with a dental syringe in order to keep the teeth dry. On the third application of the syringe an explosion occurred at the back of the boy's throat; acute haemorrhage followed, and he died within ten minutes. The light at which the syringe was warmed was fully six feet away from the operation table, there was no naked flame near, and the surgeon satisfied himself that the syringe was not red-hot. Death was due to rupture of the bronchi and collapse of the lungs. In our issue of November 28th (p. 1034) a correspondent suggested that ignition of the ether vapour and oxygen might have been due to catalytic action on the surface of a warm platinum syringe needle, or that in the absence of platinum some metallic part of the syringe might have acted in a similar manner. On December 26th (p. 1246) another correspondent suggested that the explosion of the anaesthetic might have been due to a minute burning piece of wick or a drop of burning methylated spirit being carried on the end of the hot-air syringe. We have now received from Dr. Charles F. Hadfield, honorary secretary to a joint anaesthetic committee of the Medical Research Council and the Royal Society of Medicine, a note by Professor H. B. Dixon, F.R.S., of Manchester, drawing attention to the fact that mixtures of ether vapour and oxygen will ignite at relatively low temperatures. Professor Dixon's report (which is of a preliminary nature only) is as follows: "As the Anaesthetics Committee of the Medical Research Council and of the Royal Society of Medicine have done me the honour to co-opt me as a colleague with special reference to questions concerning the ignition of gaseous mixtures used as anaesthetics, may I take the opportunity of urging the desirability, in the public interest, of issuing some warning as to the high inflammability of mixtures of ether with oxygen? It is curious how little information is given in textbooks on the temperatures at which gases inflame, and there are some puzzling discrepancies between results that have been published in scientific journals. I have been experimenting for many years with different forms of apparatus on the ignition point of vapours and gases, and for the past three years have been making researches for the Mines Department on the firing of various gases by bringing the gas and air together (after each has been separately heated) in a modified 'concentric tube' apparatus—first described in 1909. Among other vapours, I have tested ether vapour by bringing it into heated oxygen through a silica tube equally heated, and have found a delayed ignition at 220° C. (428° F.)—a figure I believe to be too high (as a minimum ignition point) rather than too low. Other observers have put the ignition point of ether in oxygen as low as 190° C. (374° F.). A peculiar difficulty exists in the determination of the

ignition point of ether mixtures, because the vapour itself decomposes rather rapidly in contact with heated surfaces, and secondly, because the mixture may undergo a partial combustion with an almost invisible flame, and this may develop into the normal luminous combustion. The late Sir William Perkin found that ether vapour began to show this incomplete burning in air at 260°C ., and Mr. A. G. White, of Messrs. Nobel's Explosives Company, has observed a 'cool flame' to start under certain conditions below 190°C . Now the normal ignition of the most inflammable mixture of ether and air has been found by several observers to occur about 360°C .,—the ignition not being violent. But ether and oxygen form highly explosive mixtures in which the detonation-wave may be rapidly set up once the flame is started. The lowest ignition point of such ether-oxygen mixtures has yet to be determined precisely, but it is obvious that there is a special danger in bringing a heated body in contact with such mixtures. That the heated body is not visibly red-hot is no guarantee of safety; the danger point begins at least 300°C . below visible redness. From the ignition temperatures so far found for mixtures of ethylene with oxygen, I believe these gases are far safer from risk of inflammation than ether-oxygen mixtures." Dr. Hadfield informs us that arrangements are being made for Professor Dixon to carry out further researches into the ignition temperatures of various anaesthetic gases; but in view of the fatal accident reported last October the committee does not feel justified in delaying publication until this work is completed. The committee expressly disclaims any wish to give an opinion as to the cause of the particular fatal accident referred to, since it is without sufficient detailed information to warrant such a course. But it points out that in this or similar cases the metal tube of the dental syringe used for drying purposes might easily be at a temperature above the danger point (200°C .) without such a possibility occurring to the mind of an operator unacquainted with the facts detailed in Professor Dixon's communication.

THE BISMUTH TREATMENT OF SYPHILIS.

THE expanding horizon of chemotherapy is already bringing into view new phenomena which are confirming and extending the brilliant speculations of Paul Ehrlich, whose pioneer work has already led to the addition of so many valuable weapons to our therapeutic armoury. Dr. H. H. Dale, in his address to the Section of Physiology at the meeting of the British Association at Toronto (*JOURNAL*, 1924, vol. ii, p. 219) referred in some detail to the investigation of the therapeutic action of bismuth by Dr. C. Levaditi, whose book on this subject we reviewed on December 27th, 1924 (p. 1203). The great progress that has been accomplished step by step was set out clearly by Dr. Levaditi in an address, entitled "New discoveries in the chemotherapy of syphilis," which he delivered to the Dermatological Section of the Royal Society of Medicine on January 21st. Commenting on some of the earlier reports of this research on March 18th, 1922 (p. 443), we drew attention to the welcome degree of restraint which characterized them; it is therefore possible to accept the present description of the success that has been achieved with the greater confidence. As the outcome of very extensive experimental work at the Pasteur Institute, Dr. Levaditi has formed the conclusion that bismuth possesses the specific power of accelerating and intensifying the production in the living organism of spirochaetal antibodies. Insoluble preparations of bismuth were found to form protein compounds, which remain in the tissues and kidneys for a very long period—a point he illustrated by numerous photomicrographs—and so was explained the prolonged and complete change in the Wassermann reaction

which is obtained by bismuth treatment, as contrasted with the transient effect following the use of arsenic, which is eliminated much more rapidly. Such antispirechaetal action appears to be correlated with the metallic atomic weights, and it has been shown that vanadium, mercury, gold, and platinum have this power similarly, though with an increased toxicity. The well known value of arsenic in the treatment of syphilis suggested that some combination of the two elements would be attended by enhanced efficiency, and the potency of stovarsol (acetyl-amino-hydroxy-phenyl-arsonic acid) as a prophylactic and curative agent was vividly illustrated by the lecturer, who then explained how, by combining this substance with a sodium-potassium-bismuth tartrate, a stable preparation had been obtained which was very suitable for therapeutic use. The new compound is a yellowish-white powder insoluble in water but soluble in alkalis; it may be used as a suspension in saline solution or oil for intramuscular injections. It has been employed with success in spirochaetal infections of man and the rabbit, and appears to be better tolerated than simpler forms of bismuth; it has proved very effective in changing a positive Wassermann reaction to a negative. The chairman, Dr. J. H. Sequeira, conveying the thanks of the Section to Dr. Levaditi for his most interesting address, drew attention to the great reduction in the cost of treatment which the new discoveries about bismuth would render possible—a point which had been already recognized in Africa in connexion with yaws and syphilis.

ABRAMS'S BOXES FOR HIRE.

UNDER the heading "A new method of treating disease" an enterprising company has lately favoured a number of medical men with a pamphlet offering to hire out to their patients at three guineas a week a modified form of the magic boxes introduced by the late Dr. Abrams of San Francisco. The name of the company has been chosen ingeniously; and further ingenuity is displayed in dealing with a matter which, on the most charitable estimate, can only be said to be still in the stage of nebular hypothesis. Thus the covering letter issued with the pamphlet begins by attributing the reluctance of medical men to acknowledge the value of Abrams's work to the manner in which it has been introduced. It is then mentioned, with an air of putting the whole thing on a scientific basis, that the "first authoritative statement as to the existence of Abrams' reaction" was made by Sir Thomas Horder at the Royal Society of Medicine on January 17th, 1925. We may remind our readers that Abrams asserted that having found, from the reaction of a spot of dried blood, the disease from which a patient suffered, he could then remove the reaction (and the disease) from the patient by means of what he called an oscilloclast. We may also recall that the conclusions arrived at by Sir Thomas Horder's committee (to quote their own words) "leave the position of the practising electronist as scientifically unsound and as ethically unjustified as it was before. They give no sanction for the use of E.R.A. in the diagnosis or in the treatment of disease. Nor does there appear to be any other sanction for this kind of practice at the present time."¹ The pamphlet and circular letter now introduce us to British-made machines to take the place of the oscilloclast of Abrams, and we read in large print that "the results obtained by it [that is, the new instrument] have far surpassed those achieved by any other form of treatment used in medical practice at the present day." Any differences of opinion on the value of the method in diagnosis are dismissed as of "merely academic interest"; treatment, it is said, does not depend on the diagnosis of a definite disease, but is merely the treatment of blood

¹ BRITISH MEDICAL JOURNAL, January 23th, 1925, p. 185.

reactions. The reaction is determined, the instrument is tuned to the reaction, and away goes the disease—at all events it usually does. The most suitable cases for treatment are “ill-health” (especially when associated with that blessed word toxæmia), rheumatoid arthritis, and osteo-arthritis; but “it is theoretically possible to treat any disease by this method,” and the pamphlet ends with notes on patients cured or relieved of various diseases, including sarcoma and disseminated sclerosis. Naturally it is added that hundreds of other cases are available. Elaborate directions are given for taking the blood specimen “from the dorsum of the terminal phalanx of the forefinger,” and a pleasant air of orthodoxy and correct procedure is conveyed by a statement that the machine cannot be supplied direct to the public, but only obtained by the patient on the prescription of a physician. Let us hope that if any medical man feels moved to employ one of these machines “under a simple hire agreement” he will endeavour to record his experiences with well balanced judgement.

ROYAL SOCIETY OF MEDICINE: HONORARY FELLOWSHIP.

At a general meeting of the Fellows of the Royal Society of Medicine held on January 19th the following seven medical men, two British and five foreign, were elected to the Honorary Fellowship of the society: Major-General Sir David Bruce, K.C.B., F.R.C.P., F.R.S.; Sir Henry Morris, Bt., F.R.C.S., a former President of the society; Dr. Fritz de Quervain, Professor of Surgery and Director of the Surgical Clinic, University of Berne; Dr. Camillo Golgi, Emeritus Professor of Histology, Royal University of Pavia (whose subsequent death we record with great regret this week); Geheim Med. Rat Dr. Karl F. J. Sudhoff, Professor of the History of Medicine, University of Leipzig; William James Mayo, M.D., D.Sc., LL.D., Surgeon and Chief of Staff, the Mayo Clinic, Rochester, Minnesota, U.S.A.; and his brother, Charles Horace Mayo, M.D., D.Sc., LL.D., Professor of Surgery, University of Minnesota, and the Mayo Clinic, Rochester.

BUREAU OF HYGIENE AND TROPICAL DISEASES.

By decision of the honorary managing committee of the Tropical Diseases Bureau, and with the approval of the Secretary of State for the Colonies, the bureau's name has been changed to “Bureau of Hygiene and Tropical Diseases.” The bureau traces its history back to 1908, when, as a result of the International Sleeping Sickness Conference of 1907, the Colonial Office founded the Sleeping Sickness Bureau, which for four years carried on its work of preparing and publishing the *Sleeping Sickness Bulletins* in a room put at its disposal by the Royal Society. Towards the end of this period it brought out also the *Kala-azar Bulletin*, and in 1912 it outgrew its accommodation and moved to the Imperial Institute. Here its scope was widely increased, and it became the Tropical Diseases Bureau, publishing in place of the journals named the *Tropical Diseases Bulletin*, now in its twenty-third volume, and the *Tropical Veterinary Bulletin*, of which thirteen volumes have appeared. In 1920 it again outgrew its quarters, and removed to what was then the new building of the Seamen's Hospital Society at 23, Endsleigh Gardens, where it now occupies rooms put at its disposal by the new School of Hygiene and Tropical Medicine. Last year the managing committee, recognizing the advances in the practice of preventive medicine, and the need of the tropical and other colonies for recent information on all branches of hygiene, decided to replace the *Sanitation* supplements of the *Tropical Diseases Bulletin*

by a monthly *Bulletin of Hygiene* planned to meet the needs of the Dominions as well as the Colonies. The new journal will make its appearance this week. Dr. J. F. C. Haslam, recently Government medical officer of health for British Guiana, has replaced Colonel A. Alcock, F.R.S., as assistant director, and is in editorial charge of the new *Bulletin*. The bureau's name is now coextensive with its activities. It may be added that the tropical diseases library of the London School of Hygiene and Tropical Medicine received 648 bound volumes during the year ending July 31st, 1925. According to the librarian's report, the number of attendances in the reading room increased by 37 per cent. over the previous year, and the library is being used in an increasing degree for reference purposes and study.

MEMORIAL TO SIR WILLIAM MACEWEN.

THE committee in charge of the arrangements for a memorial to the late Sir William Macewen intends closing the list of subscriptions at an early date. After paying for the busts, which have now been received, there is in hand a sum of about £1,400 towards the endowment of a Macewen Memorial Lectureship and, if funds permit, the institution of a Macewen medal or prize in surgery to be awarded annually to the students of Glasgow University. It is still open to those who have not yet subscribed, and who may wish to do so, to send contributions to the honorary treasurer, James Macfarlane, Esq., D.L., LL.D., Wesleyan Street, Glasgow, S.E., who will make due acknowledgement.

INDUSTRIAL MEDICINE AND SURGERY.

A LETTER published in our correspondence columns this week invites medical men interested in industrial health questions, especially medical officers to industrial firms, to join the Council of Industrial Medicine. This body came into existence in connexion with the Congress of Industrial Hygiene held in Amsterdam in September last. In a paper which was published in our columns on September 19th, 1925 (p. 530), Sir Thomas Oliver (who was president of the British Section at the Congress) detailed some of the achievements of industrial hygiene and gave an account of the legislation by which various precautions have been made compulsory in this country. There can be no question that the subject is important and that it is regarded with growing interest by industrial workers and by industrial firms. We make no doubt that the International Congress on Industrial Accidents and Diseases, which is to be held in London two years hence, will be well attended, and will excite a good deal of general interest. The two aspects, though of course related and appropriately discussed at a single congress, are not identical, for a healthy occupation may have a very high accident rate; this is illustrated by coal mining, in which the health of the workers is good but their accident rate very high. The chairman and vice-chairmen of the Council of Industrial Medicine are the British members of the permanent committee of the international congress.

A MEDICAL congress, which will be called *Journées médicales de Paris*, will meet at Paris, under the presidency of Professor F. Widai, from July 14th to 18th. The inaugural meeting will be held in the Grand Palais, when Professor Calmette will deliver an address on antituberculosis vaccination. Excursions to spas and other places of interest, including Rheims, will be organized. A detailed programme will be published later.

THE "ARCHIVES OF DISEASE IN CHILDHOOD."

Published by the British Medical Association.

NEARLY a year ago some of the medical men whose work lies chiefly among children, and who for a considerable time had felt that English work in this branch of medicine was inadequately presented by existing publications, met together, and after discussion determined to sound their colleagues on the advisability of establishing a new journal. Their aim was to collect and publish the work which was being done here in this sphere, which they knew was, from a variety of causes, overlooked and ill appreciated, not only in our own country but also abroad. Notably in the United States and Canada they had often been asked where their fellow workers in those countries could obtain some knowledge of the problems which were being attacked in Britain. The answers to their inquiries among their colleagues in various parts of the country showed that the dissatisfaction they had felt was more widely spread than had been imagined, and their tentative proposals received enthusiastic support from all quarters. Edinburgh, Glasgow, Liverpool, Manchester, Sheffield, Leeds, Newcastle, Bristol, Oxford, and Cambridge, and many other centres gave the proposal to found a new journal a warm welcome, and at once promised support to the venture. Without that assurance of welcome and support the *Archives of Disease in Childhood* would certainly not have been launched, for no one who has any knowledge of the ocean of medical publications can doubt that it is a perilous venture to furnish and equip a new vessel for a voyage on those seas.

With these promises of support the promoters of the venture cast about for means to realize their aims, and, as is not unusual, found difficulties in their path—difficulties which were suddenly, and to them unexpectedly, dissolved. Their desire to establish a new journal was at once supported, indeed accentuated, by the reception given to their proposals by the British Medical Association. They saw their difficulties vanish, and the decision of the Association last July has enabled them to produce the *Archives* earlier and in much more favourable conditions than they could have expected. The pages of the BRITISH MEDICAL JOURNAL are not, perhaps, the most appropriate place in which to celebrate the actions of the Council of the British Medical Association. But the promoters of the *Archives of Disease in Childhood* desire to take advantage of the appearance of the first number to express their gratitude for the timely help given.

The first number will be published in the first week of February. It will be edited by Dr. Hugh Thursfield (St. Bartholomew's Hospital and the Hospital for Sick Children, Great Ormond Street) and Dr. Reginald Miller (St. Mary's Hospital, London, and the Paddington Green Children's Hospital), with the help of physicians and surgeons representative of Glasgow, Edinburgh, Liverpool, and London. There is a general committee still more widely representative, including Edinburgh, Manchester, Bristol, Oxford, Cambridge, Sheffield, Birmingham, Leeds, and Newcastle-on-Tyne. The journal will be well illustrated, and the first number contains a coloured plate to illustrate a paper on hepatic cirrhosis in children, by Dr. Poynton and Dr. W. G. Wyllie. The *Archives* will appear every second month, and the annual subscription is 25s., payable to the Financial Secretary of the British Medical Association, at the House of the Association,

Tavistock Square, London, W.C.1. Application may be made by a banker's order, and a form for this purpose will be sent by the Financial Secretary on request.

The reputation of this country in the study of the diseases of children has always stood high. In the fascinating anthology which Dr. John Ruhrah of Baltimore has recently published, entitled *Pediatrics of the Past*, the names of English physicians occur with frequency, and Dr. Fielding Garrison, in his introduction to the volume, when speaking of Thomas Phaer, notes what "is common to English clinicians, his unquestionable power of localizing the salient and definite clinical aspects of a disease." The names of Phaer himself, of Glisson, Harris, Sydenham, and, in more recent times, those of West, Cheadle, Eustace Smith, and Barlow, are well known to all students of the subject. But, though the reputation for clinical knowledge and teaching still stands, it has been an obstacle to its wider growth that work, both in clinical and laboratory research, in this branch of medicine has for the most part hitherto been published in journals which exist mainly for the purposes of general medicine, and that, in consequence much good work which is done in the special sphere is overshadowed by the greater mass of more general work, or has even not been published. Sir Thomas Barlow, a name honoured wherever diseases of children are studied, has made this point clear in the introduction which he has written for the first number, and at the same time has considered some of the arguments for regarding the study of children's disease as a specialty. It is, of course, evident that it is in no sense a specialty as is, for example, ophthalmology; there is nowhere a sharp dividing line separating it from the province of general medicine. There are few indeed who would even pretend that it is so, although in practice some physicians, especially in America, have definitely made the divorce from general medicine and confine themselves to children's work alone. Yet the manifestations of disease in infancy and childhood are often so strikingly different from those of the adult that the student is compelled to acknowledge that there is a distinct, though hardly a separate, sphere. Many would, as Sir Thomas Barlow has hinted, go further, and claim that none can hope to excel in his general work who has not devoted considerable time to the study of children's ailments; that the man who confines his work to the diseases of adults is apt to fail to realize how much disease is altered in its essence by the interposition of extraneous factors; and that in the young uninjured tissues of the child the phenomena, strikingly different from those of the same illness in the adult, may often throw considerable light on the problems of later life. A notable example is afforded by acute rheumatic fever: it is no exaggeration to say that no one can understand or attempt to unravel its problems without constant reference to and study of the disease in young children.

The *Archives of Disease in Childhood* will therefore be able to concentrate the work which is being done in this country in a more accessible fashion than has hitherto been the case, and will expect to enlist the services, not only of those more especially engaged in children's work, but also of those who are concerned with the wider and more complicated problems of general medicine, whenever their studies lead them to

the consideration of embryological, physiological, or anatomical questions. The biochemical investigations which now occupy general medicine so largely have in the disorders of children a field which, however difficult to explore (and its difficulties at the age of infancy are enormous), is yet one of great promise, and at present, in this country at least, but little examined. The *Archives* has already received a paper which its editorial committee believes to be entirely new work on the difficult chemistry of sclerema, and it is hoped that such work, which has hitherto often escaped the notice of clinicians because it has appeared in non-clinical journals, may in future find its readiest means of dissemination in the pages of the new periodical.

The generosity and enterprise of the British Medical Association; the support already promised from so many centres; and the certainty that the volume and standard of the work done in this country in the study of the disorders of children are high, encourage the editorial committee to hope that the *Archives* will speedily prove a worthy peer to its elder brethren in France, Germany, and America.

The following are the contents of the first number:

- INTRODUCTION. By Sir Thomas Barlow, Bt., M.D., F.R.S.
 HEPATIC CIRRHOSIS IN CHILDREN: with special reference to the Biliary Forms. By F. J. Poynton, M.D., F.R.C.P., and W. G. Wylie, M.D., M.R.C.P. (With coloured plate.)
 ADRENALINE IN SEVERE RHEUMATIC HEART-BLOCK. By G. A. Sutherland, M.D., F.R.C.P.
 REMARKS ON THE DEFORMITY OF PES CAVUS. By A. S. Blundell Bankart, M.Ch., F.R.C.S.
 THE INCIDENCE OF RICKETS IN A LONDON HOSPITAL OUT-PATIENT DEPARTMENT. By Helen Mackay, M.D., M.R.C.P., and others.
 A NOTE ON THE CLINICAL DIAGNOSIS OF RICKETS IN INFANCY. By Helen Mackay, M.D., M.R.C.P.
 A STUDY OF RICKETS: INCIDENCE IN LONDON. By Donald Paterson, M.B., M.R.C.P., and Ruth Darby, M.B., Ch.B.
 RECENT ADVANCES IN THE DIAGNOSIS AND TREATMENT OF PURPURA HAEMORRHAGICA. By Bruce Williamson, M.D.
 KETONURIA AND URINARY ACIDITY. By Kenneth H. Tallerman, M.C., M.D., M.R.C.P.
 FOUR CASES OF IMMOBILIZATION: with Remarks on the Method. By E. I. Lloyd, M.B., B.Ch., F.R.C.S., and B. E. Schlesinger, M.B., B.Ch., M.R.C.P.
 NOTES ON MEASURES IN INFANT FEEDING. By G. A. Harrison, B.A., M.D., with Hugh Thursfield, D.M., F.R.C.P.

SUNLIGHT TREATMENT: ARTIFICIAL AND NATURAL.

AMONG a number of inquiries from readers relating to various aspects of this subject, we have had one lately from a medical man in Hertfordshire who seeks guidance as to the best form of artificial sunlight lamp, at a moderate price, for the treatment of a patient with surgical tuberculosis (psoas abscess), and as to the necessary precautions to be taken during treatment. We referred this query to Sir Henry Gauvain, medical superintendent of the Lord Mayor Treloar Cripples' Hospital and College at Alton, Hants, and he has been good enough to give the following advice:

"A cheap and simple lamp that would be likely to be of some use in the treatment of a private patient suffering from spinal caries with a psoas abscess would be a mercury vapour lamp, and the type I would recommend would be the Jesionek. The patient should first be tested for an erythema dose. This test could be most easily made by exposing small areas of one leg of the patient for two, three, four, and five minutes. Probably with a Jesionek lamp there would be erythema after three or four minutes' exposure. That should be the initial dose. Treatment can be given daily, the doses increasing a minute every day or every second day, probably up to about fifteen minutes' maximum.

In my opinion it is hardly worth while buying a lamp for one patient, and in a case such as this the doctor would probably be well advised to wait until after Easter and then start a graduated course of natural sun treatment, according to rules I issue to our nurses, of which I enclose a copy."

As many practitioners would no doubt be glad to have in detail the rules adopted at Alton, to which Sir Henry Gauvain refers, we reproduce them in full.

INSTRUCTIONS FOR THE CONDUCT OF SUN TREATMENT.

The following rules must be observed, unless other instructions are issued, or special directions given for the treatment of individual patients.

1. No new patient is to be exposed until he is acclimatized and insolation ordered.
2. The patient's head must always be protected by a canopy or sun hat.
3. The patient must never be allowed to become too hot or too cold. If he complains of the heat, his bed or stand must immediately be put in the shade; if he is faint a cold compress to be applied to the cardiac region and the medical officer on duty summoned. If he appears cold or shivers he is to be instantly covered, hot bottles applied, and current switched on if he occupies electrically heated bed.
4. Blistering the skin must be always avoided. Excessive erythema (redness) or any blistering to be immediately reported.
5. In commencing treatment, as a general rule (usually individual instructions will be given) parts of the patient's body may be exposed as follows (five, ten, or twenty minutes hourly means an exposure for either of these periods in three separate hours):
First day—Legs to knees for five minutes hourly.
Second day—Legs to knees for ten minutes hourly.
Third day—Legs to groin for ten minutes hourly, and where possible turn patient and treat other side of body as on first day.
Fourth day—Expose to groin and buttocks for ten minutes hourly. Total exposure twenty minutes hourly.
Fifth day—As on fourth day, and in addition one aspect of trunk exposed for five minutes hourly.
Sixth day—As on fifth day, and in addition other aspect of trunk exposed for five minutes hourly.
Seventh day—As on sixth day, but double exposure of trunk permissible.
Eighth day—Total exposure of trunk twenty minutes hourly permitted and exposure of legs to be increased.

Subsequently, periods of exposure may be gradually increased if the patient is pigmenting satisfactorily. When pigmentation is fully established, the patient may be completely exposed for increasing periods until he can tolerate continuous exposure, which may now be undertaken whenever sunshine is available up to a total of three hours daily, and to a limited extent even in the absence of direct sunshine. Certain cases will be found in which these rules cannot be rigidly followed, and less exposure is called for or more exposure may be tolerated. Individual instructions will be specially given for these patients.

6. If unsuitable weather supervenes which interrupts treatment, insolation must be resumed at the earliest possible moment. If pigmentation is fully established, half the exposures last given may be permitted.

7. Sinuses or ulcers should be exposed for as long as and whenever possible, as soon as pigmentation is established. Any purulent discharge must be immediately swabbed. If there are flies about or it is windy and there is any dust, sinuses or ulcers must be touched with a little iodine. The iodine is to be confined to the sinus and not swabbed over healthy skin.

8. Even in the absence of sunshine, discharging wounds on the face, neck, and extremities are to be exposed unless contrary directions are given. Dressings in these situations should be applied only at night time, or if the patient remains in the ward.

9. In any case where a patient's evening temperature exceeds 100° F., the patient must not be exposed the following day unless special orders are given.

10. A daily record should be kept of the period of exposure of each patient.

11. Patients who do not pigment, or who freckle, are to be reported and are not to continue insolation unless specially ordered.

12. Under no circumstances may a nurse leave the patients in her charge while they are receiving sun treatment.

NOTE.—It is desired that pigmentation of the skin be secured as speedily as is safely possible. That pigmentation must be maintained and intensified whenever weather conditions permit, with due regard to the above rules. These rules refer to May sun in the southern counties. At other seasons and in other districts they require modification.

COMMON SENSE.*

BY

L. G. J. MACKEY, M.D., M.R.C.P.,
PHYSICIAN, QUEEN'S HOSPITAL, BIRMINGHAM.

"SCIENCE is a first rate piece of furniture for a man's upper chamber if he has common sense on the ground floor." These words of Dr. Oliver Wendell Holmes well express what was in my mind when I chose the subject for my paper.

From the very outset of the student's life common sense is necessary; in fact it is needed before a parent can come to a decision as to the suitability of his son or daughter for a medical career. It would be an act of common sense for a boy or girl who wishes to become a doctor to ascertain the conditions of medical practice, its labours and rewards, its openings and its opportunities; yet in far too many instances the student toils through years of arduous work to find himself at last a member of a profession for which he has neither the taste, temperament, nor physique.

Common sense will tell the medical student whether he has embarked on the right career; when to work and when to play; how to choose his teachers and his books; how best to gain the necessary knowledge; how to distinguish essentials from trivialities; it will prevent him being led away by new and unproven things from simple, sound, established principles and facts; and will finally be of great help to him in passing his qualifying examinations. By this time he will have made up his mind what branch of medicine he intends to take up, and in any case will need more practical experience than he can have acquired as a student.

If he has decided to go into general practice he will take some appointment where he can make his early mistakes without disaster to the patient or himself, and at the same time gain the very necessary practical experience which can only come from daily contact with the sick. A resident post in a good hospital is invaluable at this stage, provided a man has the common sense to realize that the proportion of rare and serious cases is far higher than he is ever likely to encounter in private practice, that the surgeons and physicians are not as a rule intimately acquainted with the conditions of general practice, and that a successful autopsy, however educative to oneself, cuts very little ice with the general public.

I think we have shown a lack of common sense in failing to devise some scheme whereby a young doctor before setting up in practice could undergo a sort of post-graduate apprenticeship, say for six months, under an experienced and able practitioner. In any case let us hope that when, after some period of probation, he embarks in general practice, common sense will pilot him through his first disappointments and disillusion when he begins to realize that his favourite professors and the authors of his textbooks were obviously unacquainted with the sort of work of which general practice consists; that most people appear to suffer from complaints he never encountered in hospital; and that so large a proportion of his patients are certain to recover in any case that the scope for his medical and surgical skill is limited to a very few. Then for the first time common sense will make him realize that his professional success and reputation are going to depend more on his common sense, tact, industry, sympathy, straight dealing, and even temper, than on his skill in diagnosis and treatment; though it will also remind him that this skill is of the greatest importance and must be exercised and improved at every opportunity.

Common sense is common ground on which doctor and layman meet; it is the touchstone by which a patient tests his doctor. A patient can understand a plain, common-sense explanation of his complaint, and will willingly carry out a line of treatment which satisfies his common sense. Lack of common sense on the part of the doctor is invariably detected and not easily forgotten or forgiven.

COMMON SENSE IN DIAGNOSIS.

A correct diagnosis is a good start in tackling a case, but the public do not realize the difficulty which we often encounter in making it. What, then, is one to do when faced with the question, "What is the matter?" at a time when we do not know the answer? One does not satisfy the patient by saying quite frankly, "I do not know," for he may think you are concealing something from him, or that he can get a better answer by going to another doctor. Besides, it is always possible to tell him what you *do* know, and how you propose finding out still more; thus common sense here comes to our rescue and enables us to satisfy the patient while we make further investigations or more commonly wait a little longer for further evidence; "Time is the third leg of diagnosis." But it is neither common sense nor straight dealing to put the patient off with a diagnosis which we do not believe ourselves. If in genuine doubt as to the seriousness of the complaint common sense whispers "Safety first"—I mean safety for the patient; keep an eye on him, perhaps put him to bed; a few days in bed hurts no one and helps to cure most things. Should an illness develop seriously it is some satisfaction to recall that the patient had been put to bed at the beginning of it rather than allow him to visit you until sheer weakness made further visits impossible. In all cases of pyrexia, severe pain, breathlessness, diarrhoea, vomiting, jaundice, hæmorrhage, sore throat, rheumatism in children and young people, and many other conditions, common sense tells us that bed is the right place.

In making a diagnosis let us always remember that patients usually suffer from common diseases, and be chary of diagnosing rarities. For example, let us see how common sense applies in the diagnosis of hæmoptysis.

A young person has coughed up a little blood, and your medical knowledge tells you that the case is *probably* one of pulmonary tuberculosis. If the patient has not valvular disease of the heart, has had no recent illness making an infarct probable, and nothing suggesting pneumonia, the diagnosis becomes practically a certainty—it is pulmonary tuberculosis. You examine the lungs to find physical signs of a lesion and you find nothing; common sense here must tell you that in large organs like the lungs a small tuberculous focus may give no signs at all, so do not be influenced by a negative examination—stick to your diagnosis. Forget for the moment the textbooks that tell you of slight impairment of resonance, the slight diminution of breath sounds; you did not find them, so do not imagine them.

Do not take "No" for an answer when you ask the patient if he spits up any phlegm; give him a sputum pot and tell him to cough first thing in the morning and expectorate into it. You will be surprised how frequently you can get a fair sample of sputum. Perhaps it is too soon to expect tubercle bacilli—but common sense says perhaps it is not, and at any rate it cannot hurt to try. Well, suppose no tubercle bacilli are found in the sputum even after several examinations—all the better for the patient. After all, tuberculosis is an *infection*, and common sense tells us that there should be some of the common signs of an infection—look for them. Pyrexia—a temperature of 99° or more about 4, 5, or 6 p.m.—some sense of weakness or lack of usual energy, perhaps anaemia, breathlessness, lack of appetite, sweating; a previous history of pleurisy, a bad family history—any of these with hæmoptysis makes tuberculosis so near a certainty that we can reasonably act upon it.

But suppose we have made a mistake and labelled a man tuberculous who has nothing the matter with him except hæmoptysis from some unknown cause, have we done him any harm? No; a restful fresh-air holiday, a period of careful observation cannot do harm, and if we have tackled him properly he will not be alarmed or depressed. Suppose, on the other hand, we have let him go on working, waiting for something more definite to develop before making so serious a diagnosis, have we done any harm? Probably; for as a rule after hæmoptysis tuberculosis advances till treatment begins.

So common sense tells us that, with certain obvious exceptions, hæmoptysis means a diagnosis of pulmonary tuberculosis; and common sense has told me for many years that

* A paper read before the Coventry Division of the British Medical Association, November 3rd, 1925.

the luckiest phthisical patient is he who gets his haemoptysis at the beginning of his infection. Does not common sense also tell us that pulmonary tuberculosis has acquired its evil reputation because it is often diagnosed too late, whilst we on our part hesitate to diagnose it on the flimsy evidence available in its early stages because of its evil reputation, and so the vicious circle is completed? Cannot common sense do something to break it?

Diagnosis is tending to become daily more accurate and more complicated, thanks to radiography, bacteriology, and biochemistry; and although it is obviously impossible for every doctor to carry out radiological and laboratory investigations for himself it is very important for him to know when they are likely to be useful.

Radiography may fail to confirm a diagnosis, though that diagnosis is obviously correct. Gall stones, renal and bladder calculi, some ulcers of the stomach and duodenum do not necessarily reveal themselves in a skiagram, and a patient who has been advised to undergo an operation is apt to be confused by the negative finding unless the situation is clearly explained to him before he is x-rayed. It may be asked, Why resort to the trouble and expense of x rays if you are certain that your diagnosis is correct? The answer is, that at present the patient is unaware of the difficulties of radiological diagnosis, and he naturally expects a doctor to avail himself of this means of confirming his diagnosis before submitting him to the ordeal of an operation. In this instance, and many others, common sense should remind us that the public are not well acquainted with the merits and limitations of modern methods of investigations and treatment, and it is impossible sometimes to refuse a request which is rational and logical from their point of view even when it seems rather superfluous to us. The matter is quite on another footing when they want something which we believe to be harmful.

When it is necessary to send something to a laboratory it is important to know how the specimen should be collected and exactly what is required; it shows a lack of common sense to send blood or urine or a swab in such a way as to make a reliable examination impossible. Some things can be safely sent by post—for example, sputum for tubercle bacilli, a swab for diphtheria bacilli, or blood for the Wassermann reaction. Other things may become useless after slight delay—for example, nasal swabs in cases of catarrh, sputum that requires examination for any germs other than tubercle bacilli, and blood for cultures; but in all cases the laboratory should get the specimen as fresh as possible. The common-sense reason is, that while some germs die quickly at lower temperatures than the body, others multiply with great rapidity, and so we get the extraordinary paradox that cultures made from a fresh warm nasal swab may show a profuse and practically pure growth of pneumococcus, while cultures made after a few hours' delay show a profuse growth of staphylococcus and no pneumococci at all. Again, urine which when fresh is normal in every way and microscopically free from any germs, may after twenty-four hours in warm weather be crammed with bacteria even though kept in a sterilized bottle.

There is room for common sense in the matter of collecting samples of urine for bacteriological and microscopical examination. If an ordinary sample shows no deposit on centrifugalization, and no germs by microscope or culture, there can be no need for a catheter specimen. In a man the meatus can practically always be cleaned sufficiently to make the catheter superfluous, though exceptionally a catheter sample may be wanted to examine for tubercle bacilli. In a woman there is nearly always contamination from the vagina or vulva; pus, epithelium, and germs get into the urine from those sources, and can only be avoided by taking a catheter specimen. Bacteria make urine turbid; speaking generally, it may be asserted that urine which is as clear as whisky when viewed in a clean glass is not infected.

It seems only common sense to learn beforehand what sort of a specimen the bacteriologist or biochemist requires before asking him to examine it. A little common sense could usefully be incorporated in the bacteriologist's report. For example, in reporting that a tonsil swab shows a profuse culture of streptococci, he might often usefully

add that vast numbers of streptococci are present normally in every throat; or in reporting that cultures from a catheter specimen of urine show several colonies of *B. coli*, he might usefully add that such a finding is probably not of the slightest significance; and if blood shows a pure culture of *Staphylococcus albus* it might help to point out that this germ is undoubtedly only a contamination from the patient's skin. To send a tooth in a sterilized receptacle to a bacteriologist and expect him to find the nature of the infection which was at its apex previous to extraction is ridiculous, but it does not appear so unless we are superficially acquainted with the bacteriology of normal gums and teeth.

Common sense tells us that a correct diagnosis should explain all the patient's symptoms, and that whilst, as a rule, these are due to one disease, yet it is no law of nature that a patient should have only one disease at a time; how frequently is functional disorder harnessed to organic disease!

COMMON SENSE IN TREATMENT.

Vis medicatrix naturae—that wonderful natural power of recovery—is usually working on behalf of the patient, though not always fast enough to satisfy him or you. So that in most cases it is only necessary to follow the most common-sense advice that was ever given: "*Primum non nocere*"—see that your treatment does no harm (perhaps we might add the words "on balance," for we may have to do the patient a good deal of harm—amputate a limb, for example—in order to do him good).

To my mind treatment divides itself into two main classes: (1) Removal of anything tending to tax the patient's strength and lessen his natural powers of recovery. (2) Adding something to the patient to give him more power to fight his disease.

The first class seems to me the more important; it includes all surgical operations, the removal of dirt, pain, exertion, strain, worry, sleeplessness. Our treatment of typhoid fever and pulmonary tuberculosis, for example, amounts to removing from the patient all debilitating stresses except those due to the poisonous effects of the bacillus itself, which at present we are unable to remove. Take an everyday example of a patient complaining of some discomfort after food. We may give him some rhubarb and soda and at once relieve him, but it is unlikely that we have removed the cause of his discomfort or prevented the return of his symptoms. Just a little more time, a little more common sense, and we may light on the cause of his complaint; we might at any rate see if his teeth are bad, or if he is drinking too much, or if his meals are badly spaced, and if so tell him frankly that these are faults which must be rectified before he can expect to be cured.

In a case of neurasthenia it may be extremely difficult to discover where the fault lies, and before we can cure the patient it may be necessary to discover and remove some hidden worry or anxiety, some obscure infection, some bad habit, or perhaps some foolish fear. It is in such cases that common sense comes to the rescue and effects a cure that no amount of drugs alone could achieve. Common sense tells us that we should always examine our methods of treatment from this point of view. Have we really done anything to help the patient, have we tried to remove something which is harming him?

Take a case of pneumonia. Can we add anything to the patient which will increase his fighting power? I think we may answer, "Nothing that is certain to do so"; and although drugs, vaccines, and alcohol have ardent advocates they have still more ardent opponents. So we will avoid controversy and agree that we must be doing right if we carefully conserve what natural strength the patient has for the great fight before him.

Now is the time for judgement and common sense. Shall the patient remain at home, where adequate nursing seems impossible, or be removed to a hospital replete with every modern convenience? Let each case be judged on its merits, but, speaking generally, I regard a case of pneumonia as the worst possible case for hospital treatment: the distressing journey, the strange surroundings, the

proximity of the dying, the noises of the ward, strange foods at strange hours, washing and changing, fatiguing examinations by strange doctors—all these things sap a patient's fighting power and discount the advantages which hospital treatment affords. Personal experience is a most fallacious test in pneumonia, yet I must frankly confess that I have seen recoveries take place in the lowest slums of Birmingham that I should have deemed impossible in hospital. I am inclined to think that a patient with acute pneumonia fights better in the atmosphere to which he is accustomed.

Now how can we spare his strength? By easing pain and cough and giving sleep. Again we must take each case on its merits; a poultice does good and can do no harm if it can be applied without pulling the patient about; but what about morphine? I think there are times when it is safe and times when it is fatal. Cough may be troublesome, yet may be better than no cough; sleeplessness is wearing, yet sleep may be purchased too dearly. Many a time have I begged a patient to make the best of his pain and sleeplessness because I dare not do more to soothe him.

Do you examine the chest in pneumonia? Of course you do; yet who of us can ever remember discovering anything by that examination, say, during the first week, which made the slightest difference to our treatment? A stethoscope applied to the front of the chest hurts no one, but to sit the patient up or turn him over fatigues him, makes him cough, may give him pain, and always increases the pulse rate. A time may come when you may have to look for an empyema, but that is later.

In all or most hospitals it is the custom to place screens round a patient when he is using the bed-pan; in private cases the doctor usually keeps out of the room on such occasions. This is the only excuse I can offer for my own ignorance for many years of the exhausting effects of defaecation in pneumonia. I rather fancy that of all the complications of pneumonia a brisk saline purge on the sixth day is the most fatal. These patients are usually constipated, and unless we can give some adequate reason for interference I fail to see why we should disturb them by aperients or enemata. We all agree that a suitable diet is a light one leaving little residue; abdominal distension is exceptional—why, then, insist on several actions of the bowels during one week? Perhaps it is because few of us have seen how comfortable such a patient may remain whose bowels have not acted between the rigor and the crisis.

We are becoming embarrassed by the wealth of proprietary remedies and medicines, glandular extracts, vaccines, foods, vitamins, advertised in the medical press and brought to our notice by seductive samples. While there can be no harm in giving a fair trial to a new remedy if we are satisfied that it cannot hurt our patients, we must do so with an open mind, unbiased and uninfluenced by the almost miraculous properties that may be claimed for it in advertisements and leaflets.

It is the soundest common sense to cultivate the habit of regarding every case from the patient's point of view. To detect behind some trivial complaints the patient's dread of cancer, serious disease, nay, even death, and be able to send him away cheerful and satisfied, is one of the greatest rewards that fall to our lot. It is common sense which tells us to treat patients and not diseases. It is common sense which enables those of us who are neither very clever nor very skilful to attain success by being safe, punctual, and cheerful.

Let me end by pointing out the situation when we doctors display our greatest lack of common sense—it is in dealing with our own ailments, especially by neglecting to take ordinary care of ourselves at the onset of common infections. I have seen many tragedies from this cause. Every one of us ought to realize that any day he may be suddenly taken ill, and common sense demands that he should make such arrangements beforehand that his commitments shall not prevent him going straight to bed and receiving just the same consideration as he would show a patient. I am not here to suggest a remedy, but I should have thought that adequate insurance against sickness and a friendly arrangement beforehand with neighbouring colleagues was common sense.

THE UNIVERSITY OF LEEDS.

GROWTH OF THE UNIVERSITY.

At a time when the University of Leeds is endeavouring to raise no less a sum than half a million pounds a few remarks as to its genesis will not be out of place. In the early seventies a few far-seeing Leeds men started the Yorkshire College of Science, and it is on record that at first there were three professors and for some forty-eight hours there was but one student, who was shortly joined by three others. Progress was rapid, and after some years the scope of the college was widened by the addition of a department of arts to those of science and technology, while the name was altered to that of "The Yorkshire College." The Leeds School of Medicine, founded in 1831, had for many years been carrying on excellent work, and with a wise foresight college and school united in the year 1884. This union carried with it certain improvements both in the college and in the school and paved the way for the admission of the Yorkshire College as a constituent college of the Victoria University, the other colleges of which were the Owens College of Manchester and the University College of Liverpool. The relations of the three colleges were always very cordial, and when Liverpool expressed a wish to cut the painter it came rather as a shock to Leeds, especially as Manchester, very reasonably, followed the action of Liverpool with the demand for a separate university for that city. Charters therefore were in rapid succession granted, and Leeds became the seat of an independent university in the year 1904. There can be no doubt whatever that the progress that Leeds has made since that date has more than justified the action that was taken. In the words of the appeal which has been issued,

"The growth of the university has been remarkable. The present number of whole-time students (over 1,400) is more than twice the number in attendance in 1913-14. During the same period the teaching and research staff has risen from 178 to 268. Departments have expanded and new departments have been added to the equipment of the university. The field of knowledge covered by the university contains over forty separate departments and about a hundred subjects of investigation."

Infirmiry and University.

The appeal for the large sum of £500,000 which has been launched is fully justified by the urgent necessity which exists for new buildings and for extensions of the present premises. The library—and here we are speaking of the general library, and not of that which is housed at the School of Medicine—is quite inadequate, and becomes more so year by year, and many of the departments for teaching and for research are inadequately housed. It is, however, with the development of the medical school of the university that we are mainly concerned. During the last few years the relationship between the Leeds General Infirmiry and the School of Medicine, always cordial and advantageous to both institutions, has become more intimate by the teaching in the infirmiry, and all that relates thereto, being taken over by the university; the members of the honorary staff are all clinical lecturers of the university—not, however, *ex officio*; they are appointed individually to the position. Many of the lectures formerly given at the school are now given in a modified form at the infirmiry. The pathological work of the infirmiry is carried on in the infirmiry laboratories by the university staff under the direction of the professor of pathology, who is also honorary pathologist to the infirmiry, for, as the rule of the infirmiry quaintly runs, "Every candidate for the post of honorary pathologist must be the professor of pathology at the University of Leeds." The union between the university and the infirmiry is therefore so intimate, and so certain to be permanent, that it is hoped that any structural alterations which may be necessary at the infirmiry in respect of teaching may be carried out by the university. But apart from this it is the definite intention of the university to build and equip an up-to-date pathological block on ground adjoining both the present school of medicine and the general infirmiry, which are next one another.

The dental department, which during the last few years has made great progress, is sadly lacking in accommodation, and much of that which it enjoys is provided

temporarily by the infirmary authorities. This will soon be remedied. On a site given by the infirmary the university has undertaken the responsibility of erecting a dental hospital fully equipped for the treatment of patients and for the teaching of students. Some details of this scheme will be given in a future issue. Financial support has come in part from private sources, in which the dental profession has set a good example.

The appeal of the university for half a million pounds was launched at a public meeting presided over by H.R.H. the Duke of York in October. It is gratifying to know that in the period of three months no less than £262,000 has been promised. A very pleasing feature in the subscription list is the representation on it of the members of the teaching staff and of former students who, having grasped their indebtedness to the university, desire that others shall have better opportunities for acquiring knowledge than they themselves could get.

CANCER CAMPAIGN IN YORKSHIRE.

In connexion with the British Empire Cancer Campaign a movement has been started for the establishment of a cancer research centre for Yorkshire, and it has been decided that this shall be in close connexion with the Medical School of the University of Leeds. Viscount Lascelles gave a luncheon at the Queen's Hotel on January 18th, which was attended by a very large number of influential people. Sir Berkeley Moynihan, chairman of the council, explained the objects of the research centre, and emphasized the necessity for it to be immediately associated with, if indeed not actually an integral part of, the university. Lord Lascelles was able to announce that a sum of £23,000 had been promised before the meeting. The meeting was then addressed by Sir Algernon Firth, who had been a generous donor to the university fund. He had been in conversation with the university authorities, and as a result of this he read the following letter:

"It is my intention, in order to further the objects of the Yorkshire Council of Cancer Research, and to assist them in securing their objective and to ensure that research is made possible, to give, through that council, to the Leeds University £20,000, to be applied, together with £5,000 promised to the university as per my letter of July 23rd, 1925, towards the erection of a pathological institute in which special laboratory accommodation will be provided for persons engaged in cancer research work."

This generous contribution stimulated the meeting to respond to the appeal of Lord Lascelles, and very shortly promises of donations were handed in which brought up the amount promised before the meeting to upwards of £30,000. With Sir Algernon's donation, therefore, the Yorkshire council starts with over £55,000. The sum which was mentioned as a minimum for the efficient carrying out of the work was £75,000, and there is little doubt that this will be forthcoming in time. The meeting was also addressed by Sir George Newman, who expressed the gratification of the Ministry of Health with the efforts which were being made all over the country, and by Dr. Gye, who spoke optimistically as to the future. At a subsequent meeting, held at the Medical School, the staff and the students had an opportunity of hearing from Dr. Gye a short lecture on the work upon which he had been engaged.

THE PROPHYLACTIC VALUE OF SCARLET FEVER ANTITOXIN.

SINCE April of 1922 it has been the general custom not to send into isolation hospitals patients from Tottenham suffering from scarlet fever. Thus from March till December, 1922, of the 919 patients notified during the whole year, 608 were nursed at home and treated there by the council's nursing staff by eucalyptus inunction and carbolic oil swabbing of the throat. Similarly, in 1923, of 335 cases notified, 347 were treated at home.

I want to say at once that I was not entirely satisfied with this form of treatment because of the frequency with which secondary cases occurred. To be precise, in 1922 there were 22 secondary cases notified between the date

of notification of the primary case and the thirteenth week thereafter; and 55 secondary cases were notified in 1923 between the primary notification and the end of the twenty-first week. In 1924, of the 367 notified cases, 295 were treated at home with 21 secondary cases.

My purpose in mentioning these facts is to show that there was favourable opportunity afforded in this locality to put to the test the efficacy of any treatment that claimed to be prophylactic against scarlet fever; and I take this opportunity of thanking the medical practitioners of the district for their co-operation, without which my efforts would have been in vain.

Late in 1923 my attention was drawn to the work of Sindoni, Cristina, and Caronia in Rome on measles and scarlet fever (*La Pediatria*, xxxi, Nos. 14 and 15), but I was unable to obtain material for trial.

In May, 1924, Dr. MacConkey, of the Serum Department of the Lister Institute, obtained from Dr. Dochez (of New York) a culture of his *Streptococcus haemolyticus scarlatinae*, and at once immunized horses by Dochez's method. Dr. MacConkey also received two bottles of serum (about 30 c.cm. each) from Dr. Dochez and passed one on to me. It is the result of my experience with this serum, and later with that supplied from the Lister Institute, that I desire to submit.

Fourteen contacts with 5 scarlet fever patients were given 2 c.cm. each of Dochez's serum intramuscularly.

One developed scarlet fever, mild attack, on the day following inoculation.

One showed a slight general reaction: rash on joints of arms and legs; temperature subnormal.

One showed a severe reaction: joint pains, extensive rash, collapse, and albuminuria for three days. This child had previously suffered from diphtheria and had had diphtheria antitoxin. It is suggested that there was in this case a sensitiveness to horse serum.

Eleven showed no reaction other than at the seat of inoculation (vastus externus)—redness, swelling, and stiffness for two or three days.

Of 101 contacts with patients in forty-five premises who were inoculated each with 2 c.cm. of serum derived from the animals of the Lister Institute, 10 contracted scarlet fever, in one instance as late as seven months after inoculation. In the remaining 9 the periods after inoculation in which the disease developed were as follows:

In two members of the same family the period was 11 and 12 days respectively.

In four members of one family the period was 6, 6, 7, and 9 days.

In the three remaining patients the period was 6, 9, and 5 days respectively.

Six showed symptoms suggestive of scarlet fever:

(a) This child was unwell previous to inoculation and on the same day developed a slight blush on the body and an injected throat, followed by powdery desquamation.

(b) This case had a profuse nasal discharge previous to inoculation and the injected throat and suggestive tongue. Three days later (October 21st, 1924) the temperature was 99.4°. There was powdery desquamation on October 23rd.

(c) Twenty-four days after inoculation enlarged cervical glands; no rash observed, but twenty-six days after inoculation slight desquamation.

(d) Rash on chest and behind the ears. No sore throat or other symptoms.

(e) Sore throat and vomiting same day as inoculation; four days later the patient was well. Powdery desquamation.

(f) Twelve days after inoculation there was slight rash; no sore throat, no rise in temperature.

Six showed slight general reaction. Puffiness of face, general blotchy rash from about the fifth to the twelfth day after inoculation. One of these cases had been treated with diphtheria antitoxin two years previously.

Seventy-nine showed no reaction other than at the seat of inoculation.

It was manifest that the serum was either of no value or that it was not given in sufficient quantity. In the case of the two children in the same family who developed scarlet fever on the sixth day, and in three other instances,

an area of about the size of the palm of the hand at the site of inoculation had the natural skin colour in the midst of an otherwise general scarlet rash (Schultz-Charlton reaction). If, then, the Schultz-Charlton reaction is a true indication of the specificity of the serum, it seemed probable that it was the dosage that was at fault.

Supplies of serum from the Lister Institute were increased, and it was thus made possible for us to employ larger doses.

Three contacts in association with three scarlatinal patients were given 5 c.cm. each. Two of the contacts had no reaction other than local; the other developed scarlet fever on the day of inoculation.

One contact was given 9 c.cm.; this was followed six days later by a mild general reaction.

Thirty-four contacts with 17 patients were given 10 c.cm. of unconcentrated serum, with the following results:

No general reaction in	16
Slight reaction in	13
Marked reaction (they had previously suffered from diphtheria) in	2
Symptoms of scarlet fever in	3

Of the three who showed symptoms of scarlet fever, one had sore throat (diagnosed as follicular tonsillitis) thirteen days later, and rash, followed by desquamation. Another had ulceration of mouth and sore throat (also diagnosed as follicular tonsillitis). The third had a rash which disappeared following an aperient (constipation for three days); there was no sore throat.

The administration of 10 c.cm. into the leg muscles of children was accompanied by some degree of tension and consequent discomfort, and it was sought to concentrate the serum.

As there is no animal test for the strength of the scarlet fever antitoxin, the serum can be tested only on susceptible human beings—that is, on volunteers who have never had scarlet fever. There are obvious difficulties in the way of obtaining these, and so the concentration of the serum was estimated by the reduction in bulk, of which the final volume was equal to one-quarter of that of the original serum. This concentrated serum was administered to 140 contacts with 41 patients as follows:

Received 2½ c.cm.	5
Received 3 c.cm.	55
Received 4 c.cm.	1
Received 5 c.cm.	79

Those who received 2½ c.cm. had no general reaction. Of those who received 3 c.cm., 49 showed no reaction, 5 had a slight reaction, and one had a modified attack of scarlet fever fourteen days later. The contact who received 4 c.cm. had a slight reaction. Of those who were given 5 c.cm., 64 had no reaction and 15 showed a slight reaction.

In addition to the above contacts I inoculated 131 school children derived from school classes where scarlet fever cases were recurring with unhappy frequency. The response to my offer to inoculate school contacts was greater than I had anticipated, about 50 per cent. consents being received. The teachers were instructed to space out the inoculated children alternately with the others. From the time of the inoculation no further cases occurred in the school for a fortnight, and all the inoculated escaped infection.

Comments.

The stiffness of the leg is obviated by administration deep into the glutei muscles.

Concentration has the effect of reducing the frequency and degree of general reaction. The local reaction with concentrated serum in the buttock is negligible.

The dosage of serum for prophylactic purposes is not less than 3 c.cm. concentrated.

It is too early to be dogmatic, but I am disposed to believe (1) that scarlet fever antitoxin is specific against scarlet fever; (2) that when given intramuscularly in 5 c.cm. doses (of concentrated serum) it protects for at least fourteen days.

[FROM OUR SPECIAL CORRESPONDENT.]

Campaign against Tuberculosis.

A new sanatorium for university students is being erected in the French Alps above Grenoble. In response to a strong appeal, money enough has been collected, and the medical profession has subscribed very generously for the purpose, the importance of which it is particularly well able to understand. M. Masson, the well known medical publisher, has received the subscriptions, and the list is still open. It is hoped that the sanatorium will be in a position to welcome its first patients very shortly. The amount subscribed by the medical profession in France is all the more remarkable in view of the difficult financial position of the French doctor, described in my last letter. Not only has he to face personal difficulties which are continually increasing, but he has to include in his budget a tax which, though not imposed by law, nevertheless constitutes a very pressing obligation; I refer to the pecuniary aid he is bound to extend to all those doctors who, by reason of age or of bad health, cannot support themselves. They are infinitely to be pitied. In addition to the assurance companies, we have a number of professional associations which undertake to provide their members, in return for a contribution paid during the whole of the active period of their lives, with an income in their old age, which, if it does not make them rich, is at least sufficient to allow them to live in a proper manner in retirement. The fall in the value of the franc, combined with the increased cost of living, has reduced the real value of their pension by 90 per cent., and this means poverty. Thus is produced an obligation which weighs heavily on the shoulders of the whole medical profession.

The establishment of this new sanatorium is an important addition to our antituberculous armoury. It is well known that our country ran a special risk at the time when the war ended, for its territory had been a *bouillon de culture* for germs brought from all the four corners of the world. This risk appealed particularly to our American friends, who, under the auspices of the Rockefeller Foundation, brought us both technical and financial aid. The organization of the campaign against tuberculosis now carried on in France is due to the enthusiastic efforts of a statesman who died only a few weeks ago, Léon Bourgeois. The work of the Comité National de Défense contre la Tuberculose extends throughout every part of France; since the war it has established 580 dispensaries, which control 32,000 beds for tuberculous persons. It will be remembered that it was at the invitation of this committee in 1920 that thirty-four countries adhered to the Union Internationale contre la Tuberculose. The duties of a medical officer of a dispensary are very analogous to those of a tuberculosis officer in Great Britain. The number of French sanatoriums for pulmonary tuberculosis is 75; of these establishments, 45 are private and 30 public; together they possess 7,230 beds. This number is nevertheless wholly insufficient; according to the American formula the number of beds in sanatoriums ought to equal half the annual number of deaths from the disease. From the most recent statistics available it would appear that the number of deaths from tuberculosis per annum in France is 84,000, so that there ought to be six times as many beds. Recent information as to the results of sanatorium treatment is to be found in the important book of that apostle of the method, Dr. Guinard, physician to the sanatorium at Bligny.* Among the cases of tuberculosis of the first degree the results are very satisfactory, since 89.4 per cent. recover; among those of the second degree the rate is 14.2 per cent. These figures are no doubt encouraging. But if we have regard to all those in whose sputum the tubercle bacillus is found, it appears that at the end of ten years 76.6 per cent. are dead, so that though the results are good in the most favourable conditions, in the end we have to register a terrible mortality. That a very analogous result is reached in cases treated by artificial

* A review of Dr. Guinard's book *La Pratique des Sanatoriums* is printed at page 197 of this issue.

216 JAN. 30, 1926]

pneumothorax is shown by a recent report of M. Naveau on an examination of the statistics in the service of Dr. Rist in Paris. After ten years 71 per cent. of such patients are dead. The harrowing conclusion is that for a patient suffering from established tuberculosis treated in the best possible way the chance of survival after ten years is 50 per cent. if his attack is slight, and 30 per cent. if his attack is more serious and he is treated by the production of artificial pneumothorax. As the prognosis is so gloomy common sense suggests that everything must be done to prevent the onset of tuberculosis; it is plain, therefore, that all our efforts must be directed towards preventive treatment; prevention is the policy to which we must come if we wish effectually to combat this scourge of tuberculosis.

The Birth Rate.

... of the Chamber of Deputies is always a member, and this year again Pinard carried out his duty.

The Birth Rate.
Chamber

The first meeting of the Chamber of Deputies is always presided over by the oldest member, and this year again this was a medical member. Professor Pinard carries lightly the weight of his eighty-four years, and took advantage of the occasion to impress on the representatives of the country the doctrine he has so often impressed on his students when he was professor of obstetrics in the Paris medical faculty. From the tribune of the Chamber he discussed the grave questions of the birth rate, of the protection of the mother, and of the care of early infancy, telling his fellow members that the first of all political questions is that the nation should have citizens.

Sea Voyages.
Médical

Our venerable Académie de Médecine, fine old lady as she is, is not devoid of a certain sense of humour. In the advice it has recently given on the best way of avoiding sea-sickness we find a reflection of the teachings of Rabelais. Dr. Loir, having in a recent paper praised the therapeutic value of long sea voyages, had to admit that they had at least one inconvenience—sea-sickness. About this the *Bulletin* of the Académie (December 29th, 1925) contained the following note: "According to M. Loir, sea-sickness is caused by the disorderly modifications which happen in the movement of ships. For treatment, therefore, by long sea voyages it is important to choose ships which do not obey the movements of the waves, and routes on which the sea is little agitated."

England and Wales

PRESENTATION TO PROFESSOR RUTHERFORD MORISON.

THE firm place that Professor Rutherford Morison holds in the hearts of colleagues, practitioners, and students in the North of England was shown by the large and representative gathering on the occasion of the presentation of a testimonial to him at the College of Medicine, Newcastle-on-Tyne, on January 21st. The testimonial took the form of his portrait in oils, and a cheque for £1,100. The company numbered some 300 men and women, and among them were veterans in practice who had witnessed Mr. Morison's early beginnings in surgery, and could, no doubt, recall benefits received at his hands in years gone by. Many old house-surgeons, and among them his first house-surgeon, were present to honour their chief. From the industrial districts of Tyne-side, and from the hills and dales of Northumberland and Durham, and even from Cumberland and Yorkshire, doctors had journeyed to bear tribute to Professor Morison, to show their personal regard and affection for him, and their pride in his achievements and in the prestige he has brought to the Newcastle School of Surgery. Students too, with whom no teacher has been more popular, formed a large and enthusiastic part of the audience. On the platform with the guest of honour were the chairman of the testimonial fund, Professor H. Brunton Angus, Professor Howden, Dr. James Hudson, representing the British Medical Association, and Mr. R. J. Willan, the treasurer and honorary secretary of the fund. It was announced that the testimonial fund, which was limited to the medical profession, had met with a striking response from practitioners and old students in

D WALES. A portrait of Mr. Morison was painted by Mr. Harold Knight, and there remained a balance in the fund of about £1,100; the mode of the disposal of this sum was left to Mr. Morison to determine. By resolution of the subscribers it was agreed to leave the execution of the plan chosen by Mr. Morison to the executive committee. A photograph of the portrait has been made. The committee requests that any who may wish for copies should apply immediately to the honorary secretary of the fund (6, Kensington Terrace, Newcastle-on-Tyne).

The presentation speech was delivered by Professor Bruntun Angus, who, at the conclusion of his address, unveiled the portrait, and asked Mr. Morison's acceptance of it, at the same time handing him a cheque for the balance of the fund. In an eloquent speech, couched in warm and generous terms, Mr. Angus sketched Rutherford Morison's career from the time when, in 1867, he forsook general practice in Hartlepool to take up surgery in Newcastle. He began at once to teach the students, who soon learnt that they had a master in their midst, and were held in thrall by his simple, yet practical, methods; he then laid the foundation of the reputation as a great teacher which he has held ever since. In 1888 he was elected to the surgical staff of the old Royal Infirmary, and by his great surgical skill and prowess he soon made a reputation as an operator. No operation was too formidable for him; nothing daunted him; and the greatness of his faith began to spread among the practitioners of the North of England, and they sent him work in increasing amounts. By his writings and teachings he so impressed the leaders of surgery all over the world that they must recognize that when they came to England they must visit Newcastle. In other words, he made Newcastle famous. He trained a band of disciples in his own methods, and inspired them with his own ideals and zeal. Many of these, like their master, have since attained to eminence. He retired from the active staff of the infirmary in 1913, but he did not therefore rest on his oars or live on his past reputation, for the outbreak of war in 1914 called him forward to organize the Gosforth War Hospital. There he worked in his old strenuous way, and one of his great achievements was the introduction of the "hip" treatment of wounds, a method which was extensively adopted by the armies in France and other fields. Morison later went to France to demonstrate his technique. Even now, in his retirement, he devoted himself to paediatric work at the Gosforth Cripples' Home, and had recently published a most helpful book on Abdominal Pelvic Surgery for Practitioners.

paedic work at the General Hospital, Glasgow, recently published a most helpful *Pelvic Surgery for Practitioners*. In conclusion, Mr. Angus said: "Look back on the past and you will find that the progress of the last 20 years has been a most remarkable one."

medic work at the
recently published a most helpful
Pelvic Surgery for Practitioners.
In conclusion, Mr. Angus said:
"You, Sir, can look back on a life well spent. You
used your talents nobly and well. When the history of
this school comes to be written the name of Rutherford
Morison will stand out like a bright star. The subscribers
to this fund desire to show their admiration for your work
and their personal affection towards you this day. On
their behalf I have to ask you to accept this portrait of
yourself, which they hope will keep green your memory
to those who come after. Also I ask you to accept this
cheque for £1,100. In doing so, we would pray that you
may long be spared to see the results of your life's work."
Professor Rutherford Morison, on rising to return thanks,
was greeted with enthusiastic applause. He said: "I cannot
thank you properly for the great kindness you have shown
me to-day, but there is no honour and no distinction
which has given me so much pleasure as the gift with which
you are presenting me to-day." He hoped that some
place might be found to hang the portrait in the College
of Medicine. He was anxious to live to see the new College
of Medicine started in Newcastle. Mr. Morison expressed
the view that the day of the general surgeon was
over, with which he said Dr. C. H. Mayo had, in a recent
conversation, concurred, and that in future a man must
take up a specialty. He gave interesting reminiscences
of his house-surgeon days in Edinburgh, fifty-one years ago,
to illustrate the enormous advances in surgery since then.
In five years only two abdominal operations were per-
formed. He saw both operations. It was regarded as

miraculous that one patient recovered. The other died on the fifth day, and on *post-mortem* examination Mr. Morison found septic peritonitis, for which no cause could be ascribed. "We did not know then," he said, "that these things came from dirty finger-nails and dirty instruments." Speaking of the practice of medicine in general, he said: "The medical profession is the most important unit in the community. As soon as it is recognized that health counts before wealth, the doctors will come into their own." He went on to refer to the introduction of the Insurance Act, and said that the lesson learnt during that controversy was that they could do nothing without an organization. He spoke of the importance and strength of the British Medical Association, and commended its extension abroad through its Branches in the colonies. Mr. Morison concluded his vigorous and stimulating address by an interesting sketch of life's journey in the form of a parable, in which he likened it to the ascent of Mount Everest, directing his remarks particularly to the students present. "What you are going to be and going to do is the first thing to decide. The next thing is to carry on towards the goal in view. You must have courage—a courage that may sometimes flinch, but never falter. And that courage must be combined with faith, persistence, and perseverance."

Votes of thanks concluded a ceremony which will live long in the memories of those present. The portrait, which is a beautiful example of the art and a striking likeness, was much admired. Mr. Morison, whom all present were glad to see looking so well, was warmly greeted by many of his old friends and students after the meeting.

THE WORK OF A SURGICAL UNIT.

At a meeting of the Cardiff Medical Society held on January 19th, Mr. A. W. Sheen, professor of surgery in the Welsh National School of Medicine, gave an address entitled "Some aspects of three and a quarter years' work of the surgical unit." The address was based on an analysis of 1,807 admissions into the surgical unit beds of the Cardiff Royal Infirmary during the period October 1st, 1921 (the date of inception of the unit), to December 31st, 1924. He first drew attention to the value of hospital records, and recommended their being kept on a uniform system by all hospitals, using the official *Nomenclature of Diseases* as the basis of classification. Dry lists were of little use—they must be analysed, abstracted, and commented on, and a "follow-up" system was essential. A broad numerical statement was shown on blackboards indicating the frequency of the different classes of cases. Some interesting points in this were the frequency of abdominal cases, which formed 40 per cent. of the total; this preponderance was largely due to 264 admissions for appendicitis. Primary injuries, particularly fractures, gave 22 per cent., and cancers of all kinds 9 per cent. Half the admission were "emergencies" and half "non-emergencies." The operations numbered 1,645; there were 135 post-operative deaths. A detailed analysis of all the admissions had been prepared and was distributed to each member of the audience; Professor Sheen went through this, drawing attention to the lessons to be learned for surgeons and practitioners. He spoke in more detail of various groups of interesting cases and of other groups, such as fractures, which had been followed up over a long period. He expressed the hope in conclusion that medical men or medical teams in other fields of practice would on future dates give to the society a picture of their work. An animated discussion followed, in which Dr. Cameron (the President), Professor Kennedy, Dr. Picken, Dr. Ivor Davies, and Dr. Bowen-Jones took part.

WELSH HOSPITALS REUNION DINNER.

The first reunion dinner of the Welsh hospitals was held at the Royal Hotel, Cardiff, on Saturday, January 16th. Colonel A. W. Sheen, who commanded the Netley and overseas hospitals, presided, and was supported by Lieut.-Colonel H. G. Cook, who succeeded him in the command of the Netley Hospital; by Sir William J. Thomas, the greatest benefactor of the hospital; by Alderman J. Robinson, who as Lord Mayor of Cardiff gave the lead to, and throughout supported, the hospitals; and by a repre-

sentative company of all ranks. Over a hundred attended, and a very enjoyable gathering of old comrades took place. Colonel Sheen, proposing the toast "To the Memory of the Hospitals," reminded his hearers that the Welsh hospital was the first voluntary hospital in the war, its inception dating from August 8th, 1914. He spoke of the excellence of the Netley buildings, which were often used as a model for others, and referred appreciatively to the work of the architects, Messrs. Edwin and Stanley Hall. He recalled those who lost their lives on service, and spoke in detail of the work of the overseas hospital in India, with its 3,000 beds. Lieut.-Colonel Cook reminded the company of the 300 beds in the Netley Hospital, which endured until March, 1919, while Private Frank Williams voiced the regard felt for the hospitals by the rank and file. Captain Garfield Evans proposed "The Guests," and Sir Wm. J. Thomas and Alderman Robinson responded; while the final toast, by Major John Owen, paid tribute to the work of the ladies and the nursing staff, and was acknowledged by Mrs. A. W. Sheen and Sister Chitham. The dinner produced many interesting meetings of those who had served together, and there was a universal hope that future gatherings of a like kind would take place.

THE WELSH NATIONAL MEDICAL SCHOOL.

The conference between those in favour of the constitution of the Welsh National Medical School as an independent school of the university and those opposed to it, arranged by the meeting at Llandrindod last autumn of the Court of Governors of the university, was held, or perhaps it would be more correct to say began, in Cardiff on January 15th. The Court of Governors of the university contemplates the preparation of a draft charter, being of opinion that the full development of the school as a national centre for medical education and research could best be obtained by constituting it an independent school in the university. The official report of the conference in Cardiff states that the representatives of Cardiff College reaffirmed and maintained their opinion against the principle of separation. On some points agreement was reached, but on others fundamental differences were discovered. The conference lasted all day, but no definite decision was reached, but it was arranged that each party in the conference should discuss separately the various points raised. To the question, What was meant by an independent school in the university? it was answered that it would involve the entire transference to the medical school of the departments of physiology and anatomy in the faculty of science of the college.

Scotland.

ROYAL COLLEGE OF PHYSICIANS: ANNUAL DINNER.

The annual dinner of the Royal College of Physicians of Edinburgh was held on January 22nd in the College of Physicians Hall. Professor G. M. Robertson, President of the College, occupied the chair, while Sir Robert Philip, Vice-President, Sir Norman Walker, Treasurer, and Dr. George Gibson, the Secretary, acted as croupiers. Dr. Lewis C. Bruce proposed the toast of "The Imperial Forces," to which Vice-Admiral Sir Walter Cowan, K.C.B., and Lieut.-General Sir William Leishman, K.C.B., replied. The toast of "The City of Edinburgh" was proposed by Professor G. Lovell Gulland, C.M.G., and acknowledged by the Lord Provost, Sir William Sleigh. The toast of "Our Guests" was proposed by Sir Robert Philip, and responded to by the Rev. James Harvey, D.D., Moderator of the United Free Church, Sheriff M'Clure, K.C., and Sir Robert Bolam, Chairman of Council of the British Medical Association. The list of toasts concluded with that of the Royal College of Physicians and its President, proposed by Lord Ashmore.

LABORATORY FOR GLASGOW MATERNITY HOSPITAL.

An extension of the Royal Maternity and Women's Hospital at Rottenrow in Glasgow was opened on January 19th by Lady Blythwood at a meeting over which the Lord Provost, Sir Matthew W. Montgomery, presided. The new building has three stories, and consists of rooms

for administration and for the residence of the house superintendent and resident medical staff in its lower two stories, while the top flat is devoted to laboratory purposes. The establishment of the laboratory is mainly due to a bequest left some twelve years ago by the late Mr. William Robertson, shipowner. It consists of chemical, general, and private research laboratories, together with accessory accommodation for incubators, sterilizers, etc. Sir Donald MacAlister, Principal of Glasgow University, speaking on the advantages which the laboratory would confer, remarked that one important function of a laboratory was in regard to the diagnosis and treatment of individual patients, but the second, even more important, object was the prevention of the maladies from which these patients suffered. No effective prevention was possible unless they knew the cause at work and found how it might be neutralized or averted. Certain forms of infection of the blood and tissues to which mothers were specially subjected gave rise to much illness, ending frequently in death, and caused family tragedies in every rank of society. These tragedies would continue until they knew more about the cause and about the conditions which favoured their onset. Dr. Cruickshank, director of the laboratory, said that out of 24,000 mothers admitted to the hospital within the last ten years, 1,920 individuals, or 8 per cent., had suffered from dangerous and often fatal forms of blood poisoning. In addition, 850 individuals had suffered from eclampsia. It would be one of the objects of the laboratory to endeavour to distinguish and trace to their source these forms of poisoning. He thought that it would be possible to find accommodation for the development of teaching of both graduates and undergraduates in the many and complex methods and results of scientific inquiry into problems which midwifery still presented.

THE JAMES MACKENZIE INSTITUTE, ST. ANDREWS.
